1. The tubercle bacillus does not pass through normal renal epithelium.
2. The tubercle bacillus appears in the urine only when tuberculous lesions exist either in the urinary tract or in the genital tract.

THE TREATMENT OF INOPERABLE AND POSTOPERATIVE TUBERCULOSIS OF URINARY TRACT *

STANLEY L. WANG, M.D.
NEW YORK

This is a description of the methods of the treatment of inoperable and postoperative urologic tuberculosis as it is administered at the Urological Department (James Buchanan Brady Foundation) of the New York Hospital.

During the spring of 1926 a special department was established for the investigation and treatment of inoperable and postoperative urologic tuberculosis. This department was established for the following reasons:

It had been found that urogenital tuberculosis is an increasingly important part of urologic work. The modern methods of diagnosis, such as the determination of renal function, genito-urinary roentgenologic studies, the wider usage of guinea-pig inoculations, etc., have shown that the genito-urinary tract is a not infrequent site for tuberculosis. It has therefore followed that a larger number of these patients are appearing for care and treatment.

The treatment of genito-urinary tuberculosis is essentially surgical when the tuberculous lesion can be entirely extirpated in an individual who is healthy otherwise and the local tuberculous lesion is not part of a general active tuberculosis. That is the accepted treatment today and there is ample support in medical literature to uphold it. But there are a number of patients who have bilateral lesions or other additional foci of active tuberculosis and are thus as a rule inoperable. In addition to the inoperable patients, the after-treatment of those who have been operated on is frequently prolonged and requires special local and general treatment.

* Read before the Rockaway Medical Society, Dec. 17, 1926, Lawrence, Long Island, N. Y.

* From the Department of Urology (James Buchanan Brady Foundation) New York Hospital.

At the New York Hospital there have long been ample and adequate facilities for the diagnosis and surgical treatment of urologic tuberculosis. The inoperable and postoperative patients had heretofore been cared for in conjunction with the general urologic cases.

In view of the steadily diminishing general death rate of tuberculosis it seems that the measures taken to care for the disease are succeeding, so it was decided to establish this special department for these inoperable and postoperative urologic tuberculous patients and to utilize the general treatment of tuberculosis together with the special urologic care. Thus the reason for the establishment of the new department, which is apparently one of the first of its kind, is for the purpose of combining with the urologic treatment the procedures that have been found to be of value in the treatment of general tuberculosis.

As the result of this plan, the treatment of the inoperable and postoperative patients is administered along two lines, the special urologic treatment and the general and special treatment of tuberculosis.

The special urologic treatment is carried on by the urologist, Dr. William R. Delzell, who is associated with this department. The treatment varies according to the indications in each case but it may be described as including bladder irrigations, bladder instillations, prostatic treatments, fulguration of bladder ulcers, cystoscopic observations and ureteral catheterizations. A number of the patients suffer considerably from tuberculous cystitis as a complication, and the palliation of this distressing condition while the general tuberculosis treatment is being carried on is one of the difficult urologic problems. A great many remedies and procedures have been tried without very much success. At present methylene blue is administered internally and applied locally in the form of an alkaline instillation and it is giving fairly good results.

The general treatment of tuberculosis, that is, fresh air, rest and good food, is prescribed for all patients. They are advised to remain in the open air as much as they can and to sleep in a well ventilated room. The value of rest is emphasized to each patient, and they are urged to rest regular periods daily. Diets are suggested as indicated; that is, where it seems advisable to increase weight, foods are recommended for that purpose. The diet problem is increased by the necessity at times of selecting foods that will not irritate the diseased genito-urinary tract.

It is, of course, difficult to carry out the fresh air, rest and dietary care of tuberculosis systematically outside a sanatorium; nevertheless, constantly stressing these measures is productive of good results.

In addition to the general treatment of tuberculosis, some of the special measures that are in use to treat the disease are also utilized. Tuberculin is administered in suitable cases. Koch's old tuberculin is prepared in serial dilutions and given hypodermically. Good reports have been made of the value of tuberculin in the treatment of this type of patients at some of the European clinics, and it has a place in the treatment of selected cases. Avoidance of reactions, which implies careful use of tuberculin, seems to give the best results when this subsidiary agent is being used.

Another of the special measures is the mercury vapor quartz lamp, and it is very useful. It is almost a specific in the treatment of postoperative tuberculous sinuses of the genito-urinary tract. The sinuses following nephrectomy for renal tuberculosis, epidymectomy and orchidectomy for tuberculosis yield readily to the lamp treatment. Bilateral tuberculosis of the epididymides or testes either before or after the disease has suppurated and formed external sinuses can well be given this treatment with the idea that it will help to localize and arrest the lesion as well as to help prevent its further extension.

The mercury vapor quartz lamp is also used for tuberculous cystitis, applied in the same manner as in the treatment of tuberculosis of the intestine, in which it has given good results. The tuberculous cystitis patients are given biweekly treatments over the bladder region. It is planned to also try intrabladder treatment for these patients, with a special applicator and the water cooled mercury vapor quartz lamp. The inoperable renal tuberculosis patients are given lamp treatments over the kidney regions. The results from this type of treatment are as yet uncertain, but the patients seem to feel that they are benefited.

Heliotherapy is a very valuable adjunct, and when it is feasible it is added to the general care. Sun treatment of patients with disease of the genito-urinary tract is of course difficult to carry out in a large city where the patients are living at home.

The foregoing is a brief outline of the treatment of postoperative and inoperable urologic tuberculosis as we are administering it. Better to describe the kind of cases under treatment, a few representative types have been selected.

REPORT OF CASES

The first patient has inoperable bilateral renal tuberculosis:

Case 1.—A woman, aged 24, married, Italian, whose family and past personal history are irrelevant, began to have dull aching pain in both kidney regions during October, 1925, frequency of urination both day and night, burning on urination, noticeable hematuria at times, and she seemed to lose strength. During January, 1926, she came under the care of Dr. Oswald S. Lowsley. Cystoscopy showed cystitis. The phenolsulphonphthalein test and urea test to determine the renal function showed that the right kidney seemed to be functioning correctly but the left kidney function was diminished. The roentgenologic study, which included pictures of the entire genito-urinary tract with pyelograms, was indicative of renal tuberculosis. Guinea-pig inoculations with urine from the right ureter and from the left ureter were positive for tuberculosis.

It was decided that the patient had bilateral renal tuberculosis which was inoperable, and she went away to the country for a few months. During April, 1926, she became a patient at the urologic tuberculosis clinic. She was advised regarding fresh air, rest, diet and heliotherapy. She attended the clinic twice each week and has been given serial dilutions of old tuberculin hypodermically and biweekly treatment with the mercury vapor quartz lamp over the bladder and kidney regions. One grain (0.065 Gm.) of methylene blue three times a day was prescribed five days each week for the burning and painful urination.

She improved a great deal and has only occasional bladder pains and no urinary symptoms except frequency. She has gained 16 pounds (7 Kg.) and has regained considerable strength.

The next case is descriptive of the postoperative treatment following nephrectomy for uncomplicated unilateral renal tuberculosis:

Case 2—A man, aged 40, married, Irish American, stone worker, whose family and past personal history are irrelevant, noticed in October, 1925, that the urine was dark red This persisted and was not accompanied by pain, dysuria, frequency, burning of urination or any other symptoms He did not lose weight or strength and his appetite was good He consulted his private physician soon after the onset of the hematuria, but it did not clear up under ordinary therapeutic procedures He consulted Dr Lowsley during March, 1926 Cystoscopy showed the vesical fundus slightly congested, the ureteral orifices prominent, and near the ureteral ridge a little sacculation of the right one, the vesical orifice showed moderate intrusion of the subcervical group with a little irritation on the surface The function tests showed diminution of the function of the right kidney as follows The urine from the right ureter appeared milky and contained only 2 5 Gm of urea per liter, while the urine from the left ureter was clear and contained 11 Gm of urea per liter The phenolsulphonphthalein appeared from the right ureter in seven minutes and there was only a faint trace excreted in ten minutes, while it appeared from the left ureter in four minutes and 11 per cent was excreted in ten minutes Guinea pig inoculations from each ureter were negative for tuberculosis The roentgenologic study showed the right kidney large and in good position, the left kidney did not appear very clearly but it also seemed to be large and in good position there was no evidence of stone in the urinary tract In the right pyelogram there was a marked filling defect in the middle calix, the lower calix was dilated and shaggy and the upper calix also showed a filling defect about the size of one's finger, with dilatation of the upper part as if there was an abscess present, the right ureterogram showed a distortion at about the level of the third lumbar vertebra

Under regional anesthesia right nephrectomy was done by Dr Lowsley, April 16 and the pathologic report of the resected kidney was "renal tuberculosis" After a short stay in the hospital the patient was referred to the urologic tuberculosis clinic for treatment of a sinus in the nephrectomy wound, which was discharging pus Mercury vapor quartz lamp treatment was instituted and he was treated twice each week, the length of the exposures being gradually increased and the distance of the lamp varied according to the reactions

After a course of the treatment, the sinus closed The patient regained his former weight and strength and has returned to his work, free from all symptoms

Case 3 is descriptive of the somewhat different postoperative treatment following nephrectomy for renal tuberculosis when there was a mild, probably beginning, tuberculous cystitis as a complication

Case 3—A man, aged 48, married, Italian, houseman, whose family and past personal histories are not relevant, began to have pain in the right kidney region about two years ago, which continued for two months and subsided There was no recurrence until May, 1926, when the pain returned and radiated to the region of the bladder The pain continued, and during July he developed frequency and incontinence of urine Cystoscopy showed evidence of inflammation in the trigon Elsewhere the bladder seemed normal except in the region of the right ureteral orifice, which was bulging into the bladder in a cervix-like manner and exuding a plug of tenacious pus The function of the right kidney was diminished, as shown by the function tests, the urea test was not definitely indicative, but in the phenolsulphonphthalein test the dye appeared from the right ureter in nine minutes and only 2 per cent was excreted in ten minutes, while from the left ureter it appeared in six minutes and 5 per cent was excreted in ten minutes Guinea pig inoculations from each ureter were negative for tuberculosis The roentgenologic examination showed both kidneys normal in size and position, and the only evidence of stone in the urinary tract was a circular shadow in the right kidney region about the size of one's thumb The right pyelogram extended to the circular shadow and gave the impression that it was a calcified tuberculous abscess in the right kidney, it showed dilated major and minor calices, with several filling defects and shagginess indicative of tuberculosis The right ureterogram showed a dilated ureter, which was distorted, and there were several points where there were filling defects suggestive of the presence of tuberculous granulations

Under regional anesthesia, right nephrectomy and right ureterectomy were done, August 3, by Dr Lowsley. The pathologist's report of the resected kidney and ureter was 'tuberculosis of the kidney and ureter and calculi in the pelvis of the ureter" After three weeks' convalescence he returned to his home, having been referred to the urologic tuberculosis clinic for further care and observation At the clinic he was advised regarding rest, fresh air and diet, and was given serial dilutions of old tuberculin hypodermically and mercury vapor quartz lamp treatments twice each week over the bladder region and nephrectomy wound Methylene blue, 1 grain (0 065 Gm) three times a day for five days was prescribed, together with weekly instillations of 1 per cent methylene blue in 3 per cent saline solution into the bladder

The patient became free from symptoms, the wound closed, and he returned to his work, apparently well He is still under observation and care, as it is probably advisable to carry this on for a year to prevent possible recurrence

Patient 4 has tuberculous cystitis and tuberculosis of the remaining kidney after nephrectomy for tuberculosis two years ago This is a not infrequent type in urologic work, and while the results of treatment are not all that could be hoped for, alleviation of the symptoms is very comforting to the patient and there is always the possibility that an arrest of the disease may be obtained

Case 4—A woman, aged 40, married, Norwegian, housewife, whose father is said to have tuberculosis, had a cough six years before the onset of her present trouble, the cough continued for several months, and pulmonary tuberculosis was diagnosed She states that she regained her health after about a six months' rest cure, part of which time was spent at Saranac Lake During November, 1924, she had six attacks of sharp pain in the left side radiating to the back, the attacks lasted for an hour or so and there was a slight increase in the frequency of urination One month later she had frequency of urination both day and night, but no dysuria In February, 1925, she developed a steady pain in the bladder and great frequency of urination both day and night, with dysuria One and a half weeks before her entrance to the hospital, Feb 27, 1925, she had another attack of left side pain followed by hematuria, which persisted, the pain in the left side became a steady ache The physical examination of the lung at that time indicated fibroid tuberculosis Cystoscopy showed a velvety appearance of the bladder mucosa and ulcerations in the region of the trigon Tests showed diminished function of the left kidney. The urine from the right ureter was clear and contained 3 Gm of urea per liter, while the urine from the left ureter appeared to have pus in it and contained 2 Gm of urea per liter Phenolsulphonphthalein appeared in the urine from the right ureter in four minutes, and 12 per cent was excreted in ten minutes, but on the left side it appeared in four and one-half minutes and 10 per cent was excreted in ten minutes Guinea-pig inoculations with urine from the left ureter were positive for tuberculosis, they were negative from the right ureter The roentgenologic study showed the kidneys apparently of normal size and in the normal positions The left pyelogram indicated an excavation in the region of the middle calix, the upper and lower calices seemed normal The left ureter was thickened and widened; there was no evidence of stone

Under regional anesthesia, left nephrectomy was performed by Dr Lowsley, March 10, and the pathologist reported that the resected kidney showed renal tuberculosis After a short period of convalescence she returned to her home A sinus from the nephrectomy wound drained for a time but healed under the mercury vapor quartz lamp treatment The frequency of urination and the dysuria were lessened but did not clear up completely

During the spring of 1926 she was referred to the urologic tuberculosis clinic by Dr Frederick F Lau Her symptoms were frequency of urination, burning on urination, occasional attacks of pain in the bladder, and hematuria at times. She was advised regarding rest, fresh air, diet and heliotherapy, and she has been given treatments with the mercury vapor quartz lamp; also old tuberculin hypodermically in graduated doses. Methylene blue was prescribed for relief of the burning on urination.

At present she seems to be in fairly good condition and is probably holding her own. Guinea-pig inculation with the bladder urine was recently positive for tuberculosis, and she has frequently a dull ache in the region of the remaining kidney, which is apparently involved. The general and special care that she is receiving apparently help to keep her comfortable.

Case 5 is indicative of the postoperative treatment following epididymectomy for tuberculosis:

Case 5.—A man, aged 27, married, Italian, whose family history is negative for tuberculosis, had the right kidney removed five years ago, he thought possibly because of tuberculosis. During September, 1926, a swelling developed in the region of the left testis, which suppurated and drained pus through a sinus in the scrotum. It continued to drain, and on November 3 left epididymectomy and resection of the sinus were done under regional anesthesia by Dr. J. C. Pennington. The pathologist reported that the parts resected were tuberculous. After a week's convalescence in the hospital he returned home, having been advised by Dr. Pennington to report to the urologic tuberculosis clinic for further care and treatment. At that time he had a postoperative sinus in the scrotum, which was draining freely, and an inactive lesion, apparently tuberculous, in the apex of the left lung; the prostate was enlarged and nodular, and it was thought that he probably had tuberculosis of the prostate and of the seminal vesicles.

He was advised regarding fresh air, rest and diet, and he was able to arrange his affairs so that he could live in the country and visit the clinic twice each week. He has been given old tuberculin hypodermically in serial dilutions, and tonics such as cod liver oil. The mercury vapor quartz lamp treatments were given over the region of the draining sinus, and it soon healed. His general condition has apparently improved a good deal, as he feels very well and he has gained 6 pounds (2.7 Kg.). It will require a prolonged period of care and observation to determine the eventual outcome, but his present condition makes the future appear hopeful.

The last patient has tuberculosis of the remaining testis after the other testis had previously been removed because of tuberculosis. This type of case is not infrequent.

Case 6.—A man, aged 28, married, Italian, laborer, injured the right testis in 1921 while cranking an automobile. He stated that he received dispensary treatment at another hospital for about a year, and the testis was then removed at that hospital. He was informed that the testis was tuberculous. He had no further symptoms until December, 1925, when he was kicked in the left testis, which became swollen, and the swelling persisted. He was referred to the urologic tuberculosis clinic during the spring of 1926, by Dr. Thomas J. Kirwin, whom he had consulted. At that time the testis was swollen to about the size of a hen's egg, and it occasionally ached. He has now been under treatment for some little time and he has been receiving mercury vapor quartz lamp treatments and old tuberculin hypodermically in addition to the usual hygienic, dietetic and rest regimen. The swelling of the testis has lessened and his general condition is good.

COMMENT

These patients are fairly representative of the various kinds under treatment, and the procedures and methods in use. While the results are not extraordinary, they are encouraging.

The plan on which the clinic was established—the combining of the special urologic treatment together with the general and special care of tuberculosis—seems to be working out satisfactorily.

108 East Eighty-Second Street.

HYPOTENSION

REPORT OF SIX CASES IN ONE FAMILY

JOHN D. GARVIN, M.D.
PITTSBURGH

Comparatively few have been the communications in various journals on the subject of low blood pressure. As opposed to hypertension, it pales into insignificance in the niche which it occupies in medical literature. At first thought, and from an academic standpoint, this may seem lamentable. But viewed from the clinician's point of vantage, should the condition—with the extreme paucity of stigmas ascribable to the hypotension per se—command a major claim on the profession's attention? That it assumes increased significance when associated with debilitating and even fatal diseases, such as arthritis, tuberculosis and Addison's disease, is, of course, obvious. Such associations are excluded from the discussion presented here, and I speak only of that hypotension unassociated with any determinable pathologic condition: that type which may be termed "essential" or "incidental" hypotension.

With many of those who have commented on the matter of low blood pressure in recent years, the opinion is rather prevalent that it needs must occur in persons of a definite and peculiar habitus and constitution and usually referred to as asthenic, hyposthenic, with narrow chests and slender bodies, underweight and displaying "a marked inefficiency for arduous and sustained physical effort." [1]

Fossier [2] speaks of a "characteristic symptomatology" of low blood pressure which is found in the asthenic and splanchnoptotic patient and only rarely, if ever, in the hypersthenic. It is my feeling that such definite and rather sweeping conclusions are hardly justifiable and I am inclined to adhere to the views expressed by Lambert [3] and Friedlander,[4] who maintain that low blood pressure is wholly consistent with good health, and that many healthy persons have low blood pressure without showing symptoms but are indeed vigorous people. Muhlberg [5] is quoted as saying that "there appears to be no doubt of the fact that a low blood pressure past the age of 50, unassociated with any organic lesion to account for this low blood pressure, is the best criterion that we possess that the individual will live beyond his normal expectancy."

Hypotension is not necessarily confined to the asthenic person or to the patients of little efficiency. It can and does occur not infrequently in persons of normal build, of hypersthenic habitus, of quite normal efficiency, of normal weight or even in the obese; and per se, essential or incidental hypotension is attended with little or no clinical significance. Therefore its neglect, more apparent than real, at the hands of the medical commentators is, in a measure, justified. In support of these tenets I herewith present six cases of essential or incidental hypotension in one family, five of which are in one generation—three brothers and two sisters, and the sixth a son and nephew.

These observations, given in the accompanying table, were made without any preparation on the part of the patients, and represent the highest reading of the sphygmomanometer in several examinations at intervals over a period of two years. In each case they were made at or about midday, with the patient fully clothed and sitting erect.

[5] Muhlberg, William, quoted by Friedlander.

With the possible exception of the physician in the group, the family is one characterized by extreme activity, efficiency in hard work, and splendid physique, and is of a stock noteworthy for its longevity. There are absolutely no evidences of failing myocardia to which such pressures might be attributed. Particular attention is directed to that of patient 1, weighing 250 pounds, with a systolic pressure of 102. This not unusual coincidence of hypotension and obesity was noted by me in a former publication [6] wherein, out of a group of 200 definitely obese patients with and without high blood pressure, twenty-two, with weights varying from 170 to 265 pounds, had systolic pressures of 110 or under. Thirteen had pressures under 105, and eight under 100. Here, too, of course, the factor of asthenic habitus, with drooping shoulders, etc., was far removed.

Data in Six Cases of Hypotension

					Height		Blood Pressure	
		Occupation	Age	Weight	Ft.	In.	Systolic	Diastolic
1.	Mr. J. E. P.....	Merchant	65	250	5	10	102	70
2.	Mr. R. W. P....	Lawyer	60	163	6	1	96	70
3.	Miss E. M. P...	Housekeeper	59	125	5	7	108	70
4.	Mrs. C. L. G...	Housewife	57	125	5	8	94	72
5.	Mr. E. O. P....	Farmer	50	250	6		98	63
6.	Dr. D. G........	Physician	33	160	5	8	95	68

Not infrequently do we receive patients who have at some time been "put to bed by the doctor," or who have received "serum treatments" for low blood pressure. Nor is it unusual to hear from the laity the belief that "low blood pressure is worse than high blood pressure." I have heard this statement no less than three times within the last two months. Such procedures are, at best, questionable, and for such lay misunderstandings we are responsible. The subject of hypotension should be put forth in its true light, to correct any such false impressions that may have gained foothold in the medical mind and to allay needless apprehension among the laity. Let the subject assume its place along with incidental achlorhydria and visceroptosis. And just as we have well quit ourselves of hospitalizing and confining to bed, with head down and feet up, the much maligned patient with "gastroptosis," so let us assume a more rational point of view toward incidental hypotension, a condition wholly innocuous, so far as we know.

The occurrence of these six cases in one family naturally brings up the question of the possible heredity of low blood pressure. "No one who has had any contact with hypertensive cases can escape the impression that heredity plays an important rôle in the production of high blood pressure. Such an impression is obtained from observing certain families in which an extraordinary number of the individuals comprising them have died of vascular diseases." [7] A case in point is that of the husband of patient 4 and father of patient 6 in the series just given: he is a minister, aged 64, with a hypertension of 200/120, with a sister aged 63, who has a pressure of 200/110, another sister of whom died with a "stroke," whose mother died from the same cause and whose father died of "Bright's disease." In these families joined by marriage may we not have excellent evidence of the hereditary nature of both hypotensive and hypertensive conditions? On the past histories of families we must, as has been said, base our supposition of the then-existing high blood pressure, because of the relative youth of the sphygmomanometer, at least in its clinical use. In hypotension we have not even this aid that the history gives us and therefore observations on this form of vascular condition must be left for the future. I submit it, not as a fact, but rather as an hypothesis that remains to be proved—and in which proof I am making a single contribution—that incidental hypotension may be hereditary.

CONCLUSIONS

1. Six patients with low blood pressure in one family are in excellent health and are active and vigorous; most of them are robust and hypersthenic and one is obese.
2. Incidental hypotension is of little or no clinicopathologic significance, except as a possible indicator of long life.
3. Incidental hypotension has been misunderstood, in the past, and misinterpreted; and a more rational attitude toward it, both on the part of the profession and, through it, by the laity, should be adopted.
4. Hypotension, like hypertension, may be hereditary.

THE DETECTION AND INCIDENCE OF HUMAN INTESTINAL PROTOZOA BY THE SIGMOIDOSCOPE *

MOSES PAULSON, M.D.
AND
JUSTIN M. ANDREWS, Sc.D.
BALTIMORE

Although Manson-Bahr [1] has advocated the use of the sigmoidoscope in the detection of low sigmoid and upper rectal amebic ulcers, it is not apparent from the available literature that sigmoidoscopy has been used as a routine diagnostic measure to determine the presence of the intestinal protozoa in general. It is our purpose in this report to compare the incidence of protozoan parasites of the human intestine from specimens of feces obtained by the use of the sigmoidoscope with the usual defecated specimens submitted for examination. Similar procedure is being employed in the estimation and study of the bacterial flora of the large bowel.

This work was undertaken at the suggestion of Dr. Thomas R. Brown, associate professor of clinical medicine and chief of the gastro-intestinal clinic.

MATERIALS AND METHODS

The types of persons examined were extremely varied. A group of nationalities was represented which appeared at the clinic for relief of various and sundry complaints referable to the gastro-intestinal tract. None of these cases were especially selected for this study. Only eight of the 253 cases presented organic disturbances referable to the large intestine; the remainder proved to be purely functional states. A third of those examined did not present bowel symptomatology.

The physical condition of each patient on whom sigmoidoscopy was practiced for this research was such as not to contraindicate the procedure.

Each patient was placed in Haynes' position; i. e., the lower extremities remained on the table, while the trunk, flexed at the hips, was virtually at right angles to the lower extremities; the head rested on the forearms, which were flexed at the elbows and were supported by a footstool of convenient height.

It has been shown that this position is preferable to the usual, well known, knee-chest posture. In the Haynes position, the viscera are, by force of gravity, moved out of the pelvis, up toward and against the diaphragm. This reduces intrapelvic pressure and facilitates instrumentation. Although it may not be indicated by the appearance of the patient, he is actually more comfortable in this position than in the knee-chest posture.

The sigmoidoscope employed was that of Buie [2] of the Mayo Clinic. It is 25 cm. (10 inches) in length and is 16 mm. (five-eighths inch) in diameter.

In only three instances were attempts to pass the instrument unsuccessful. These cases are not included in the series. Each of them presented degrees of spasm that could not be overcome at the time of instrumentation.

The same instrument and procedure were employed in all patients whose ages ranged from 14 to 76 years. Confirming the experience of Buie, the procedure as a routine virtually did not present any difficulties. It must be urged that the sigmoidoscope should be used carefully, that force should not be employed in its passage, and that little air inflation or none at all should be used during the course of instrumentation, as perforations of pneumatic and instrumentative origins have been known to occur at the rectosigmoid junction and within the sigmoid proper, resulting in peritonitis.

Many patients were examined shortly after gastrointestinal fluoroscopy and roentgenography, and therefore presented barium sulphate, an opaque substance administered previous to these examinations, in the intestine. Clinical observations on this group make it appear that the presence of barium sulphate in the lower bowel renders sigmoidoscopy more difficult in that the contents are more tenacious and difficult to remove. It partially inhibits peristalsis and the intestine appears to be more spastic than when barium is not present.

In order to secure feces from the sigmoid, the patients were instructed to present themselves unprepared; i. e., they were not ordered to take the usual purge the night before, or to administer a soap-suds enema the morning of the examination. As a result, a large number of the patients appeared with feces in the rectum. In order to pass through the rectum into the sigmoid to secure material directly from the sigmoid by means of the sigmoidoscope, we aspirated the rectal feces, diluted with water when necessary, by means of a water suction pump. It is to be pointed out that in practically every case the instrument was inserted its full length (25 cm.), so that the specimens thus obtained were sigmoid contents, not rectal contents.

Strict asepsis in this procedure is not essential. However, the sigmoidoscope and aspirator must be sterilized after each insertion so as to avoid rectal contamination from patient to patient.

The examinations for pararsites were made as follows: Sigmoid contents were extracted by means of a tight cotton swab on a 12 inch applicator stick while the instrument was in position. One thin smear was immediately made in saline solution on a slide warmed to 99 F., and another was made in Dobell's iodine solution. The smears were examined at once under coverslips at a magnification of about 250 diameters. When organisms were located, a magnification of about 1,100 diameters was used to assist in identification. The corresponding defecated specimens were similarly diagnosed on the same day that they were obtained, so that they were examined in the majority of cases within six hours, and in all cases within twelve hours, after dejection. Only one examination was made of each specimen, the smears being searched for from five to ten minutes each. In order to reduce the personal error while comparing the parasite content from sigmoidoscopic and defecated specimens, one observer diagnosed the sigmoidoscopic specimens and another microscopist, unacquainted with the observations of the first, examined the defecated specimens.

After the smears were made, duplicate tubes of serum-saline-citrate medium [3] prepared according to the method described by Andrews [4] were inoculated. As a rule, amounts varying in size from a green pea to about half that quantity were inoculated. In a few cases in which the patient had defecated just prior to the examination or had been purged the night before, it was difficult to obtain any feces. In these instances, the medium was poured into the sigmoidoscope, and the walls of the sigmoid colon at the proximal end of the instrument were gently washed with a large capillary pipet. With the same pipet, the medium was finally aspirated and delivered into culture tubes. Similar cultures were made from the defecated specimens at the time of the microscopic examination. The culture tubes were incubated as soon as possible at 37.5 C. for forty-eight hours. At the end of that time, a large drop of the medium taken from near the bottom of the tube was examined for flagellates. Tanabe,[5] using the serum-saline-citrate medium, has shown that *Trichomonas* appears in maximum numbers forty-eight hours after inoculation. The medium appears to permit the growth of *Chilomastix mesnili* as well as *Trichomonas.*

OBSERVATIONS

In all, 253 persons were examined and bowel contents obtained by sigmoidoscope. Unfortunately it is possible to present, of this group, only 210 cases in which concomitant stool examinations could be made.

In view of the number of cases examined, this report is presented as approximating the incidence of human intestinal protozoa of this locality. This series, as judged by the chi-square test, seems sufficient to establish statistically that the two following points are not based on chance distribution; namely, that many more organisms can be found in sigmoidoscopic than in defecated specimens, and that more organisms can be found in a specimen from a clean bowel than from one that contains barium sulphate.

The distribution of nationalities was representative of the mixed population of any large city. There were about 40 per cent white Americans and about 25 per cent colored Americans. The remainder was largely composed of persons from Russia and the countries of central Europe.

The proportions of males and females were 53 and 47 per cent, respectively.

Forty-six per cent of the patients were suffering from constipation. About 30 per cent did not have symptoms referable to the gastro-intestinal tract. Twelve per cent complained of pain in the lower abdomen. Diarrhea, rectal bleeding, tapeworm, mucus and indefinite symptoms were about equally distributed as the predominating symptoms for the remaining patients. Organisms occurred throughout the various groups with an irregular frequency, indications that any one organism might be responsible for any one symptom being absent.

The ages varied from 14 to 76 years, nearly 90 per cent falling within the limits of 21 and 60. As far as is indicated by the records, the dispersion of the cases was fairly uniform. Age susceptibility was not indicated.

Table 1 shows the incidences of protozoan organisms inhabiting the alimentary tract of apparently normal persons residing in the temperate zone, grouped according to the presence or absence of barium sulphate. In the progress of this work, it appeared that the presence of such an inert substance as barium sulphate considerably reduced the incidence of protozoan organisms. Accordingly, in tabulating the results, patients were divided into two groups, one of which was composed of those who had ingested barium sulphate for the purpose of gastro-intestinal roentgenologic examination within six days of sigmoidoscopy; the other group had partaken of barium sulphate at least six days prior to the sigmoidoscopic examination, or not at all. The first subtable shows the incidence of those persons examined sigmoidoscopically who presented fecal specimens at the time of the examination and who had not partaken of barium sulphate within six days of the sigmoidoscopic examination. The second subtable presents the observations in those similarly examined but who had ingested barium sulphate within six days of sigmoidoscopy. The third tabulation is a combination of the first two and is probably more comparable with incidences revealed by ordinary routine fecal examinations.

Table 1.—*Incidence of Protozoa in Defecated and Sigmoidoscopic Specimens Grouped According to Barium Content of Bowel*

	Barium Not Given Within Six Days		Barium Given Within Six Days		Combined Barium and Non-barium Groups	
	Defecated	Sigmoid	Defecated	Sigmoid	Defecated	Sigmoid
Number of cases	95	95	115	115	210	210
	%	%	%	%	%	%
Endameba coli	4 2	21.0	3.5	13.9	3.5	17.0
Iodameba williamsi	2.1	5.3	0.0	0.0	1.0	2.4
Endolimax nana	1.1	30.5	2.6	8.7	1.9	16.2
Giardia lamblia	2.1	3.2	0.87	5.2	1.4	3 8
Chilomastix mesnili	3.2	7.4	0.87	1.7	1.9	3.3
Trichomonas hominis	4.2	5.3	1.7	1.7	2.9	2.4
All organisms	13.7	46.3	8.7	20.9	10 5	31.9

It is not to be inferred from this table that barium sulphate is actually parasiticidal. It is plain that such a comparatively large quantity of any inert, finely divided substance introduced into the alimentary tract would so dilute the contents that the chances of finding parasites per unit quantity of stool would be considerably reduced. Furthermore, it is quite possible that other factors, such as the mechanically inhibiting influence of barium sulphate on the motility and vital processes of such active organisms as the intestinal flagellates, might contribute to the difficulties of making the diagnosis.

* *Only cysts found.*

The results from making cultures for flagellates were as indicated in table 2. Nine cases of *Trichomonas* were found. With the sigmoid specimens, two were positive by smear and by culture, two were positive by smear and negative by culture, and two were negative by smear and positive by culture. From the defecated specimens, two were positive by smear and by culture, and four were positive by culture and negative by smear. Nine cases of *Chilomastix* were found, of which five were diagnosed by the presence of cysts. In these cases, cultures were not positive, perhaps because trophozoites were not present. With the sigmoid specimens, one case was positive by smear and by culture, five cases were positive by smear and negative by culture, and three cases were negative by smear and positive by culture. With the defecated specimens, one case was positive by smear and by culture, one case was positive by smear and negative by culture, and two cases were positive by culture and negative by smear. These data are presented in a much clearer form, case by case, in table 2. These results indicate that the cultural method should be used to supplement the diagnosis of flagellates by the smear method. It is not at present sufficiently refined to substitute for the smear method of diagnosis. It also appears that the medium is more reliable for the detection of *Trichomonas* than *Chilomastix*. This conclusion modestly confirms the recently published work of Hill.[6]

The absence of *Endameba histolytica* in our results is notable, and we are unable to account for it. In none of the examinations was any organism found which suggested that it might be *Endameba histolytica*. Helminth ova were not observed.

---

[6] Hill, C. M.: The Successful Application of the Culture Method to the Diagnosis of Intestinal Flagellates in the Field, Am. J. Hyg. 6: 646-658 (Sept.) 1926.

It is to be noted that *Trichomonas hominis* occurred more frequently in the defecated specimens than in those obtained sigmoidoscopically. This is accounted for by the fact that, in some of the cases, little stool or none at all was found in the sigmoid, and that, furthermore, as pointed out by Hegner and Becker[7] *Trichomonas hominis* remains viable in defecated stools three or four times as long as do other trophozoites.

In connection with these observations, it is interesting to note the incidence reported by Smithies[8] of protozoiasis in 3,780 residents of the temperate zone. Computed from this figure, the incidence is as follows: *Trichomonas hominis*, 2.0 per cent; *Cercomonas intestinalis hominis (?)*, 1.8 per cent; *Chilomastix mesnili*, 0.6 per cent; *Cercomonas* and *Chilomastix* combined, 2.5 per cent; Endameba (total), 1.6 per cent; *E. histolytica*, 1.0 per cent; *E. coli*, 0.5 per cent; unclassified endamebas, 0.08 per cent; *Balantidium coli*, 1.8 per cent; *Giardia lamblia*, 0.4 per cent. The proctoscope was used in many of these examinations, but, apparently, only with the hope of revealing gross anomalous appearances of the lower colon due to protozoan infection. It is thought that, had the instrument been used to produce the sigmoid contents, the incidences of the various organisms listed might have been somewhat higher.

It should be stated that the principal virtue of sigmoidoscopy in the diagnosis of protozoan infections lies in the fact that stool may be obtained from the sigmoid colon when it is positively fresh and may be examined immediately. While it is not possible to get all unprepared patients to defecate at will in the laboratory, it is very seldom that it is difficult to obtain abundant material for examination from the lower sigmoid of similarly unprepared patients. These specimens, examined at once, eliminate parasite mortality both while passing through the rectum and during the usual postdefecation interval before examination.

SUMMARY

1. Lower sigmoid contents have been obtained sigmoidoscopically from 253 patients, 210 of whom supplied defecated specimens as well. These specimens were examined microscopically and culturally (for flagellates), and yielded, in the group that had not partaken of barium sulphate for at least six days prior to the sigmoidoscopic examination, an incidence of all organisms of 13.7 per cent in defecated specimens, as compared with 46.3 per cent from sigmoid contents. In the group in which barium sulphate had been ingested within six days of examination, a total incidence of 8.7 per cent from defecated specimens, as compared with 20.9 per cent from sigmoidoscopic specimens, was determined. The combined barium and nonbarium groups revealed a total incidence of 10.5 per cent from defecated specimens, as compared with 31.9 per cent from the sigmoid.
2. Comparing the occurrence of protozoa found in feces obtained sigmoidoscopically and by defecation, it was found that the incidence by the former method was regularly (with the exception of *Trichomonas*) from two and one-half to three and one-half times as high as by the latter method.
3. There does not appear to be uniform association of particular organisms with particular symptoms.
4. The incidence of protozoa was approximately twice as high in those cases in which barium sulphate had not been administered, as compared with those cases in which it had been administered within six days of the examination.
5. The serum-saline-citrate method of flagellate culture was found to be a useful supplement to smear examination for *Trichomonas* and *Chilomastix*.
6. On the basis of these observations, we urge the use of the sigmoidoscope in obtaining fecal specimens for parasitologic examination. The use of this instrument for this purpose is fully justifiable in view of the proved inadequacy of single parasitologic examinations from defecated feces.

THE PRESSURE VACCINATION TECHNIC

STANLEY THOMAS, M.S.
Associate Professor of Bacteriology, Lehigh University
AND
R C. BULL, M.D.
Director, Students' Health Service, Lehigh University
BETHLEHEM, PA.

As the result of a smallpox scare at Lehigh University in February, 1924, a rule was adopted requiring every student who matriculated at the university to be vaccinated by the Students' Health Service unless he had been successfully vaccinated within the past three years. The term "successful" has been interpreted in this rule as meaning a true vaccinia, and a certificate of vaccination is not accepted unless supported by a definite scar of an obviously recent vaccinia. It was foreseen that it would be necessary to vaccinate a very large number of students (the entire enrolment of 1,400) the first year the rule was in effect and practically the entire freshman class of about 600 each succeeding year. It was also foreseen that this work would have to be carefully planned in order to develop a method of vaccination that would not interfere too much with class hours and thus bring the health service into conflict with the educational departments of the university.

Fortunately it was possible to compare various methods before the rush of vaccinating the entire student body was on us. In February, 1924, following the provisional diagnosis of a case of smallpox in the university, all contacts were vaccinated. The following technic was used: A single scratch was made, the virus was applied to the scratch, rubbed in, and then allowed to dry before the shirt sleeve was rolled down. This method was found to be satisfactory when only a few students were to be vaccinated, but the time required for the vaccine to dry, frequently as long as thirty minutes, made it impracticable when large numbers were to be vaccinated in a short time and in a limited space.

In the fall of 1924, vaccination was offered but not required and the technic which we called "jennerian" was developed. This technic is practically that which was recommended by the U. S. Public Health Service and the Medical Department of the U. S. Army. It has been thus described:[1]

---

[8] Smithies, Frank: Protozoiasis Occurring in Temperate Zone Residents: A Study of Two Hundred and Sixty-Five Instances with a Discussion of the Associated Digestive Malfunction, Am. J. Trop. Med. **6**: 1-45 (Jan.) 1926.

> The skin of the upper arm was cleansed by rubbing with a swab of cotton saturated with alcohol. This was allowed to dry. With his left hand the operator grasped, from below, the arm of the patient in the region of the insertion of the deltoid muscle. The skin was stretched and three short, parallel scratches were made about three quarters of an inch apart. The scratches penetrated the epidermis but pains were taken not to draw blood. Care was taken not to include any scar tissue from previous vaccinations in the scratched area. The virus was expelled from the tube on the two outside scratches and rubbed in thoroughly. The middle scratch was not inoculated but served as a control. It received the same degree of trauma as the two inoculated scratches.

In order to eliminate the time required for the vaccine to dry, a transparent perforated celluloid shield of large size was placed over the site of vaccination and the student allowed to roll down his sleeve at once. This procedure was not considered desirable but was used as a necessary makeshift to overcome an otherwise impossible situation. The shield was removed at the first observation of the reaction twenty-four hours later and no bad results were noted. More than 600 students were vaccinated by this method in September, 1924.

In September, 1925, the university vaccination requirement became effective and it was necessary to vaccinate more than 1,000 students. The jennerian technic had seemed satisfactory and this was followed in the majority of cases. An effort was made, however, to eliminate the objectionable features of the shield. For this purpose a special dressing was made up consisting of perforated adhesive plaster and a thin pad of gauze. The dressings were of such size that they covered the entire site of vaccination. The adhesive plaster was applied to the arm above the scratches, the gauze was then "buckled" so it did not touch the arm at the site of vaccination, and the adhesive plaster was applied immediately below the scratches. In this way the actual site of vaccination was amply protected, access of air was permitted, and the vaccine dried without an accumulation of dust under the dressing. This was of course removed after twenty-four hours. It seemed that this dressing eliminated the objectionable features of the shield and was as satisfactory as could be hoped for where protection of some kind was necessary. Nearly 900 students were vaccinated by this method.

The results obtained during the scholastic year 1924-1925 were discussed with the officials of the U. S. Public Health Service. Here we encountered the natural criticism of the use of any dressing following vaccination. It was mainly to overcome this objection that we tried out, in a limited number of cases, the "pressure" method suggested by Dr. J. P. Leake,[2] surgeon, U. S. Public Health Service. Dr. Leake's directions are as follows:

> A simple method is a shallow, tangential pricking of the cleansed but not irritated skin with a needle, through a drop of smallpox vaccine, covering an area not greater than one-eighth inch (3 mm.) in diameter. This gives little chance of accidental infection and the eruption is typical. The needle, which should be new, sharp and sterile, is not thrust into the skin but is held quite parallel or tangential to it, with the forefinger and middle finger of the right hand above the needle and the thumb below, the needle pointing to the operator's left. The needle should be crosswise of the arm, so that the thumb of the operator is not impeded by hitting the skin. The side of the needle point is then pressed into the drop about thirty times within five seconds, the needle being lifted clear of the skin each time. This rapid to and fro motion of lifting the needle and pressing it against the skin should be quite perpendicular to the skin and needle, and not in the direction of the needle. In this way the elasticity of the skin will pull a fraction of an inch of the epidermis over the point of the needle at each pressure so that the vaccine is carried into the deeper layer of epithelial cells, where multiplication takes place most easily. If the skin has not been unduly rubbed in cleansing, and if the motion is entirely perpendicular to the needle, no signs of bleeding will occur and all evidence of the punctures will fade out in less than six hours. Immediately after the punctures have been made the remaining virus is wiped off the skin with sterile gauze and the sleeve is pulled down, the whole operation of puncturing and wiping taking less than ten seconds. With strong vaccine a single pressure not infrequently gives a "take." Only six pricks or punctures were formerly advocated. Comparative tests showed this to be inferior to the scratch method in the percentage of successful "takes." By the use of thirty pricks, this difficulty has been overcome and the percentage of "takes" is as high as with any other safe method.
>
> The disadvantages of this method, which it shares with some other methods, are, first, that without demonstration and practice the technic of applying the proper pressure may not easily be acquired, and, second, that without due care an area larger than one-eighth inch (3 mm.) in diameter may be covered by the insertion. In regard to the first point, the difficulty is usually that the needle is not pressed in the right direction or that the pressure is not firm enough. Provided the needle is held quite tangential to the curve of the arm, and the direction of motion is quite perpendicular to the needle, it is difficult to make the rapid pressure too firmly. In regard to the second point, motion from the wrist with the arm held rigid is usually more accurate than whole arm motion.
>
> The advantages of the method are its mildness and painlessness, the fact that it is more rapid than any other effective and safe method, the fact that no control site is necessary since the evidence of trauma due to the operation has disappeared before the first observation for an early reaction is made, and the fact that the virus is wiped off immediately, so that the uselessness of a dressing is obvious to the person vaccinated.

The foregoing method is known by us as the pressure technic, and the fact that they were vaccinated by this method was noted on the men's vaccination record cards. As we had gotten very satisfactory results by our "jennerian" technic we were loathe to depart from it and therefore used the new technic in the vaccination of only every tenth man.

It became apparent immediately that the "pressure" technic had the practical advantage of saving considerable time. In the "jennerian" method the care necessary to avoid drawing blood, to make the degree of trauma the same in all three incisions, to rub in the virus, and to apply the dressing, took nearly forty-five seconds for each man. By the "pressure" technic a man was vaccinated and on his way in less than one fourth of this time. Moreover, the obvious ease of the method from the point of view of both the operator and the person being vaccinated was apparent to those vaccinated, and it was not unusual to have men standing in line ask to be vaccinated by what they called the "new method."

It was not until we tabulated the results of nearly a thousand vaccinations that we could draw a comparison of the efficacy of the "jennerian" and "pressure" methods. Table 1 shows the comparative results obtained by these two different methods of vaccination.

---

[1] Thomas, Stanley: Smallpox Vaccination as Carried Out at Lehigh University, Pub. Health Rep. **41**: 37 (Jan. 8) 1926.

[2] Leake, J. P.: Pub. Health Rep. **42**: 221-238 (Jan. 28) 1927.

In view of the fact that the new method is much simpler, milder, and more rapid than the old method, the comparison is remarkable. In fact, we can say that there is no difference in the results of these two methods of vaccination.

Table 1.—*Comparative Results*

	"Jennerian"		"Pressure"		Total	
	No.	Per Cent	No.	Per Cent	No.	Per Cent
Immune reactions......	576	65.5	71	66.3	647	65 8
Vaccinoid reactions.....	200	22.9	24	22.5	224	22.7
Vaccinias	102	11.6	12	11.2	114	11.5
Total	878	100.0	107	100.0	985	100.0

In February, 1926, it was necessary to vaccinate a number of men who entered the university at the beginning of the second semester. At this time the pressure technic was used exclusively. The results are given in table 2.

Table 2.—*Results with Pressure Technic*

	Number	Per Cent
Immune reactions..............................	47	75 7
Vaccinoid reactions............................	9	14 5
Vaccinias	6	9 8

While the percentage of immune reactions was slightly greater and that of the vaccinias slightly less than in table 1, the small number of vaccinations (sixty-two) must be taken into account. If the next man vaccinated had been one not previously vaccinated, we are sure that the percentage of typical takes would have been over 11 per cent.

CONCLUSIONS

1. Of the methods employed by us for the vaccination against smallpox, the pressure technic has been shown to be as efficacious as any other in inducing vaccinias in susceptible persons.

2. The pressure technic has the advantage of saving time in vaccinating a large number of persons in a short time.

3. The pressure technic overcomes the objection to the use of a dressing following vaccination and makes the dressing or shield obviously unnecessary.

4. The pressure method is more desirable from the point of view of the vaccinated person.

From these results it is our intention to adopt the pressure technic as the sole method of compulsory vaccination at Lehigh University. At the opening of college next September it will be necessary to vaccinate about 500 students. The time allowed in the schedule for this work is two hours. With sufficient clerks to make the records, two operators will easily accomplish this, using the pressure technic.

Wise Specialism an Advantage.—Wise specialism is of the greatest advantage for the progress of medicine, but its followers should know something about everything medical as well as everything about their own branch. Without taking a reactionary view, there is a danger that specialism may be exaggerated and that parts of medicine which should be within the reach of every competent medical man may be prematurely elevated into a specialty; in ancient Egypt there was a phase (500 B. C.) when each disease had its practitioner who confined his activities to that one condition. To be a clinical specialist has mercenary advantages, for practice comes earlier and the lucrative rewards may be considerable. —Rolleston, Humphry: *Lancet* 2:739 (Oct. 9) 1926.

A HARMLESS MUCOUS MEMBRANE IRRIGANT *

MARTIN H. FISCHER, M.D., Pharm.D.
CINCINNATI
AND
R. W. BLEDSOE, M.D.
COVINGTON, KY.

During the last several years the nose and throat surgeons have given up increasingly the use of irrigating solutions in the treatment of acute or chronically inflamed accessory sinuses or after these have been operated on. The feeling seems to be general that their employment is harmful, and it is frequently maintained that they spread infection. The saturated boric acid solution or the so-called physiologic salt solutions commonly used in hospitals (solutions of sodium chloride, varying in concentration from 0.7 per cent to 0.85 per cent) at times unquestionably produce such bad effects, and yet, it must appeal to every one's surgical sense that the mechanical cleansing of mucous membranes, coated with mucus or pus, can by itself be only of benefit.

In reviewing the matter some two years ago, we were of the opinion that the evil effects produced by such irrigants were dependent on their faulty composition. As commonly employed, they favor the development of an edema in the irrigated mucous membranes—a situation often aided by the overuse of epinephrine or of cocaine and its derivatives, substances which, after a brief vasoconstrictor effect, produce a long continued period of vasodilatation and, by their directly poisonous action on living cells, interfere with their normal oxidation chemistry and so aid in the development of edema. Edema in a tissue, according to W. B. Wherry's[1] observation, heightens its susceptibility to infection.

It is true of all wounds that the use of pure water on them is most favorable to the development of an edema in the irrigated parts, especially if the imbibition tendency of the tissues is increased by trauma, chemical irritants or infection. The use of salt in the water, notably sodium chloride, tends to counteract the swelling effects of the water and explains the long-known superiority of any so-called physiologic salt solution over plain water in all surgical dressing. It is too often forgotten, however, that *the uninjured cells of the human being* require a minimum of 0.85 per cent sodium chloride in the water to prevent their swelling and that, *when the cells are injured and thus have an increased tendency to swell, a sodium chloride concentration above this value must be used.*

Another fact of importance in the preparation of a proper surgical irrigation fluid is that different salts, even when employed at the same concentration, are unequally effective in reducing such swelling. The salts of magnesium, calcium and strontium, for example, are far more powerful than the corresponding salts of sodium, while still heavier metals like iron, zinc and mercury are most powerful of all. For this reason the use of a calcium salt with the sodium chloride in any irrigation fluid yields better results than the use of the sodium chloride pure. A mixture of various salts has therefore always been known to be less harmful to living tissue than any salt used singly, as exemplified in the long and favorably known solutions of Ringer or Locke. But the Ringer solutions commonly used in medical and surgical practice are physiologic mixtures derived from study of amphibian tissues (such as turtles and frogs) and are therefore of too low concentration when used on man.

---

* From the Eichberg Physiological Laboratory, University of Cincinnati College of Medicine.

[1] Wherry, W. B.: Am. J. Ophth. 8:859 (Nov.) 1925.

To obtain an irrigating fluid suitable for human use and one that took into due consideration the facts briefly outlined here, we prepared a mixture consisting of sodium chloride, 10.5; calcium chloride, 0.84; potassium chloride, 0.42; water, sufficient to make 1,000.

This solution contains the three salts which Ringer originally found so favorable for the maintenance of a physiologic activity in surviving tissues and is, in this respect, therefore, a so-called physiologically balanced mixture. The solution is also "hypertonic" in that the concentration of the sodium chloride has been raised to the point at which it will prevent not only the swelling of uninjured human cells but also somewhat above this. The concentration of the calcium chloride is several times that of the original Ringer mixture. This high value is taken in order to maintain the dehydration effects of the various salts as long as possible; for while monovalent salts, through their more rapid diffusion, affect the inflamed tissues first, the dehydrating effects of calcium last longer, once this salt has diffused into the tissues.

We find it convenient to have this solution ready in concentrated form. Powder mixtures of the several salts will not keep because calcium chloride is deliquescent. The following is a practically saturated solution of the foregoing salts in the correct proportions: sodium chloride, 263.7 Gm.; dried calcium chloride, 21 Gm.; potassium chloride, 10.6 Gm.; distilled water, sufficient to make 1,000 cc. When desired for use, 20 cc. of this mixture is diluted to 500 cc. with distilled or freshly boiled water and thoroughly mixed. We frequently use 22 cc. There is no harm in employing the solution in this or still higher concentration, but to do so in any concentration less than 20 cc. in the 500 of water is to employ a solution possessed of all the defects of plain water or an inadequately concentrated salt mixture.

It is best, of course, to irrigate with the mixture at body temperature or a few degrees higher. Since boiling does not affect it, the stock or finished solution may be readily sterilized. It is well to remember also that the diffusion of salts into tissues takes time and that prolonged contact with the tissues is favorable to this end. As much time as possible should therefore be allowed between the separate fractions of an irrigation, and the patient should be asked not to blow his nose immediately after the final one. For injection, any douche arrangement may be used; but the time element should be remembered as well as the need of using an adequate volume of the irrigating fluid (from 500 to 1,000 cc.). We have ourselves found the Holmes postnasal douche with the split tip, employed through the anterior nares, most favorable to this end. It need not be emphasized that any injection apparatus must be used with bacteriologic care, and that caution must be exercised against the aspiration of infected material into the apparatus.

Various colleagues have been using this solution in the treatment of acute and chronic infections of the head, and postoperatively, as an irrigating fluid for wound surfaces. It makes an agreeable and nonirritating wet dressing fluid which does not injure or kill new cells after burns, skin abrasions, etc. The dentists have used it to wash out extraction pockets. Howard Stitt has used it to irrigate the lungs in bronchiectasis.

Clinical Notes, Suggestions and New Instruments

ACUTE RHEUMATIC HEART DISEASE TREATED WITH STREPTOCOCCUS ANTITOXIN (SCARLET FEVER SERUM)*

Joseph H. Barach, M.D., Pittsburgh

History.—Jean C. J., aged 3½ years, referred by Dr. McCaffery of Freeport, Pa., had been taken ill three weeks prior to hospitalization with irregular fever, later occasional delirium and one mild convulsive attack, sweats, definite but not severe mobile arthritis, and myositis. The previous history was negative.

Examination.—The child was well developed and exceedingly bright, pale, and sensitive to pain. The tonsils were large and acutely inflamed, the tonsillar nodes large and tender. The lungs were normal. The heart was enlarged; there was a mitral murmur. The liver was normal. The spleen was palpable at the costal margin. The abdomen otherwise was normal. The joints of the extremities were slightly swollen but very painful and tender, especially the knees and ankles.

Course of the Disease.—There was a relapsing fever for six weeks. The eighth week was ushered in with a septic temperature curve, accompanied by daily shivering or chills, and an extremely erratic pulse ranging from 95 to 160. This continued for three weeks into the eleventh week of the disease, the patient growing worse and showing evidences of exhaustion. A severe enterocolitis developed, lasting ten days. At this time the clinical picture was thus summarized: acute rheumatism, acute tonsillitis, cervical adenitis, high and irregular fever, sweats, mobile arthritis, enlarged heart, heart murmur, precardial pains, periodic tachypnea, slight cough, large spleen, subcutaneous nodules at the finger tips and toes, and evanescent petecheal spots, seldom lasting a full day, over various portions of the body. The blood culture was sterile; weekly leukocyte counts varied between 7,200 and 9,000 per cubic millimeter. Polymorphonuclears ranged from 20 to 51 per cent; lymphocytes from 48 to 80 per cent; the hemoglobin was 65 per cent; the red blood count was 2,320,000. The urine showed occasional red blood cells. There were no evidences of nephritis. The roentgen-ray examination revealed the heart one and one-half times the normal size; the thymus shadow was considerably larger than normal; the liver was normal; the spleen extended below the costal margin; the kidney outline was normal; the frontal and maxillary sinuses were clear.

The diagnosis was: acute rheumatic heart disease with evidences of a serious endocarditis and myocarditis.

Treatment.—At the beginning, salicylates and alkalis were given, and the usual symptomatic treatment of rheumatic fever. At the end of the eighth week, when the patient was having a septic temperature such as occurs in ulcerative endocarditis, and when the enterocolitis seemed to be exhausting the patient, the condition seemed desperate.

Feb. 5, 1927, an editorial in The Journal cited a case of acute rheumatic carditis by Toogood[1] in which rapid recovery followed the use of streptococcus antitoxin (scarlet fever antitoxin). Two days later and after it had been determined that our patient was not hypersensitive to the serum, 10 cc. of scarlet fever streptococcus antitoxin-Lederle was injected intramuscularly. Within twenty-four hours the patient's temperature began to recede, reaching normal by the seventh day, and the pulse receded steadily from 140 to 110 on the seventh day. The disease seems to have ended by a typical lysis. The patient's general condition improved, appetite returned, weight increased and a final recovery seems to have taken place. This case was studied intensively by my associates, Drs. Borgman and Hook, and by the resident physician, Dr. Blough. All of us believed that we were dealing with a case of septic carditis in which recovery seemed barely possible. This was also the opinion of the family physician, Dr. McCaffery, who referred the case to me.

[1] Toogood, E. S.: Scarlet Fever Antitoxin in a Case of Endocarditis and Myocarditis, Lancet **2**: 545 (Sept. 11) 1926, cited in The Organism of Rheumatic Fever, editorial, J. A. M. A. **88**: 405 (Feb. 5) 1927.

SUMMARY

The ordinary antistreptococcic serum has been used in this type of case without success. Is it possible that scarlet fever antitoxin, which differs from antistreptococcic serum, has a specific effect other than that of a foreign protein? And is the result reported by Toogood and the result in this case *due to such specific action? Our clinical result was very striking. A patient who seemed destined to die showed a* complete change in the course of the disease and returned to normal within a week after the injection of this antitoxin.

OSTEITIS OF THE COCCYX

Frank K. Boland, M.D., Atlanta, Ga.

The report of cases of osteitis and osteomyelitis of the coccyx seems to be exceedingly rare. Monnier[1] describes a case of acute osteomyelitis of the coccyx in a girl, aged 17 years, which ran the course of an acute infectious process and which at first was diagnosed as typhoid, a mistake not infrequently made in acute osteomyelitis of other bones.

The case of chronic osteitis of the coccyx here recorded seems of unusual interest, as it was responsible for an entirely different condition; viz., stricture of the rectum. Indeed, when I first saw the patient, stricture of the rectum was the predominating lesion.

REPORT OF CASE

A man, aged 35, first noticed "soreness and sensitiveness" at the tip of the spine in December, 1923, and was more comfortable standing than sitting. He could not remember having received a blow on this part of his body, but recalled having slipped and fallen on his back on a spring-board during the *previous summer.* The pain grew more severe, and within two weeks an abscess developed over the coccyx, which was opened, Jan. 1, 1924, by Dr. J. S. Stewart, Jr., the attending physician. During the next two months, three other abscesses formed and were opened by Dr. Stewart. These continued to drain as sinuses leading down to the coccyx.

In the meantime the patient began to experience difficulty in defecation, and passed ribbon stools. Dr. Stewart found a stricture of the rectum, 3 inches above the anal orifice. The stricture was not hard and thick as in carcinoma, but was unyielding and narrow, as if a cord had been tied around the rectum at this point, reducing the lumen to about the size of the tip of the index finger. Three blood Wassermann tests were negative, and six doses of neoarsphenamine did not produce any effect on the stricture or the discharging tracts. The stricture was dilated twice a week without permanent improvement.

Roentgen-ray examination now showed an inflammatory condition of the coccyx, and on March 23, under ether anesthesia, the several sinuses were opened and excised. Three abscess pockets near the coccyx were opened. Nearly the whole of the bone apparently was diseased, and the entire bone was removed. The pathologic diagnosis of Dr. John Funke was chronic osteitis. Following the removal of the coccyx and drainage of the wound, the rectal stricture disappeared completely.

At the time of the operation no opening was found into the rectum. Fourteen months elapsed before the patient was seen again. The wound had almost healed but continued to drain, so that in May, 1925, every tract and pocket again was laid open and curetted, and still no communication with the rectum was discovered. Following this operation, after several months' drainage, every tract had closed except one. In January, 1926, this tract was opened and was found to communicate with the rectum well above the internal sphincter.

Having recently been disappointed in attempting to cure a fistula of this kind by cutting through the internal sphincter with a scalpel, I decided to try the old method of passing a ligature through the fistula into the rectum, and tying the two ends together outside the anus. Umbilical tape was used for the purpose; a single knot was tied very tightly, cutting into the sphincter, and then a single bow-knot was tied. Every third day afterward, the bow-knot was loosened and the single knot made as tight as the patient would allow. By the tenth day the ligature had cut its way entirely through the sphincter, with practically no pain to the patient. Evidently rapid union of the severed fibers took place behind the ligature, since the control of the sphincter at this time, while not complete, was very satisfactory. Three months later the patient wrote that the wound had healed perfectly and that his sphincter did not give him any trouble.

The late Dr John Wesley Long of Greensboro, N. C., told me that this method of treating rectal fistula was practiced centuries ago by an order of monks in Europe, who established great reputation by their cures. Instead of tying the ligature, however, or using a rubber band, the ligature was attached to a weight, and the patients were allowed to walk in the garden of the monastery, with the weight dangling below.

SUBCUTANEOUS EMPHYSEMA IN A CASE OF BRONCHIAL ASTHMA

I. S. Kahn, M.D., San Antonio, Texas

The rarity of this complication in bronchial asthma is the occasion for the present report. One would think that the usual violent respiratory efforts combined with the pulmonary *emphysematous condition of chronic asthma cases would produce* the condition more frequently, but such is apparently not the case. Though I have handled several hundred asthma cases in the last few years, I have never seen or heard of cutaneous emphysema resulting from this cause, and so far as I am able to learn, there are no reports in American medical literature. The only foreign references I have been able to locate are British.[1] Air infiltration of the subcutaneous tissues has, of *course, long been known to accompany other pathologic changes* of the respiratory tract.

REPORT OF CASE

G. S., a girl, aged 8, seen, Jan. 17, 1927, with Dr. R. E. Bowen of San Antonio, had had an attack of asthma that had lasted about forty-eight hours. The child had had asthmatic paroxysms every month or six weeks for the past six years. The attacks were invariably preceded by more or less typical vasomotor rhinitis.

Examination revealed the usual, heavy, generalized, bilateral râle formation, and dyspnea, of a not particularly violent attack of bronchial asthma. The heart was normal, and a general physical examination was negative. Marked air infiltration of several hours' duration existed over the upper parts of the chest and the back, over both shoulders, the neck and both sides of the lower half of the face. The appearance at first glance resembled that of well developed infectious parotitis. Crepitation over the infiltrated areas was unmistakably typical. There was no great amount of pain, but considerable tenderness on pressure. A roentgenogram of the chest, January 18, did not show a foreign body, spontaneous pneumothorax, pneumonia or other pathologic conditions, and did not reveal the location of air origin. Air could easily be seen in the fascial layers of the chest and neck.

The mother stated that this was the first asthma attack accompanied by any swelling under the skin.

The asthma yielded promptly to a single hypodermic injection *of epinephrine. As the history suggested hay-fever as an* etiologic basis of the asthma, pollen precautions were taken to avoid any recurrence, and no paroxysms succeeded the relieved attack. Under rest, ten days was required for the absorption of the infiltrated air.

Subsequent intradermal tests of the child showed positive reactions to various pollens, foods and animal epithelial emanations. There has been no recurrence of the asthma to date. The child will be watched to note whether any subsequent attacks are again accompanied by subcutaneous emphysema.

GRADUATE MEDICAL EDUCATION IN EUROPE *

LOUIS B. WILSON, M.D.
ROCHESTER, MINN.

The present report is based on my personal observations in seventeen medical centers of Europe during May, June and July of 1926, on printed material and letters from twelve other European medical centers in response to inquiries during the fall of 1926, and on personal communications from American physicians who visited these and other European medical centers during 1926.

Many American physicians are familiar with the opportunities for graduate medical education in Europe prior to the war. Hence an historical survey will be omitted and attention confined to a study of the changes that have occurred since the war, and to the present status.

CHANGES IN GRADUATE MEDICAL EDUCATION

The principal changes in conditions since the war are in:

1. The teaching personnel.
2. The mental attitude of medical teachers as affected by social depression or stimulation in their country.
3. The lack of financial resources for equipment.
4. The increased trend toward medicine of citizens recently released from military service.
5. The flood of students from southeastern Europe, Asia and Africa.
6. National antipathies developed by war.

Changes in Teaching Personnel.—Naturally, some of the great European medical teachers have died in the twelve years since 1914. It is doubtful, however, whether the mortality in this group has been greater since the beginning of the war than it was during any similar period before the war. Certainly, one visiting European countries for the first time since the war is gratified to find most of the men whom he knew before the war still alive and very active. They have grown older to be sure, but I firmly believe that in most instances these older men have maintained their mental vigor better than they would have had nothing occurred to change the routine of their lives. Of course, their total span of life may not be so long, but one is struck with the keen interest in medical science and medical education of most of even the elderly men whom one knew before the war. It is true one meets occasionally a man who is still "fighting the war," all of whose psychologic processes are skewed by his dwelling on real or fancied injustice, and whose value to medical science and medical teaching is thus greatly reduced. But such instances are rare.

There can be little doubt, however, that the crop of young men who should have made progress in scientific medicine during the half decade beginning with 1914 has been materially reduced. Indeed, the retarding period was probably two or three years longer than the period of the war itself, since immediately after the war in many countries the unsettled political and social conditions were not conducive to scientific research. However, if one may judge by the number of young men who have begun such study in the last three or four years, there will be no dearth in the near future. Indeed, not only is there a large number of eager graduate students at work but, it seems to me, their rate of work and its direction toward clinical problems has been materially augmented since 1914. Whether this research will lead to as large a proportion of dependable and desirable results as previously, one may question.

Mental Attitude of Medical Teachers Affected by Social Depression or Stimulation in Their Country.—There is no doubt that the instability of the French franc, and with it the Belgian franc, at present has a very depressing influence on scientific progress in France and Belgium. This condition was even more marked in Germany when the value of the mark was reduced to the vanishing point. But Germany and Austria, though still under a heavy financial burden, now have a fairly stabilized currency and their financial worries are therefore relatively less. The dissatisfaction of the learned classes in Austria with what they regard as their country's political isolation still has a material effect in some instances in reducing their intellectual efficiency.

In Switzerland and Holland, interest in medical education has been notably increased since the war. This is evidenced not only by the general mental attitude of medical men but also by generous public appropriations of funds for new buildings; for example, the Dermatological Institute in Zurich and the Colonial Institute in Amsterdam.

In two countries, Italy and Czechoslovakia, medical as well as other education is in that stage of elation which in the United States one associates with a general "boom." Italy, under the Fascist régime headed by Mussolini, has had a tremendous awakening of its national life. The extension of this influence to the medical profession is greatly in evidence. The Italian medical profession, during the country's long period of political and financial struggle, had always cherished a tradition of scholarship, based particularly on the fundamentals of anatomy and physiology, which had a marked influence even in its departments of purely clinical medicine. The lack of support of an intelligent public clientele, however, greatly offset the good results of this tradition. But with the tremendous reform spreading in all avenues of the social state in the last few years, cooperation of the awakened public with the medical profession has been most gratifying. I do not know of any other country in which the medical profession is more "on its toes" than the Italy of today.

Long repression of the Czech universities by German influences before the war had not killed their enthusiasm. Since they have been relieved of this repression, it is now literally bubbling over. There are, no doubt, many serious gaps in the faculties of their medical schools, and one notes the youthfulness of many of their research workers. But these youths are aging and their judgments ripening.

I am told that the conditions in Spain and Hungary resemble to some extent those in Italy and Czechoslovakia. In Spain this is because of the greatly increased wealth, and in Hungary because of the enthusiasm at national independence.

Lack of Financial Resources for Material Equipment.—In many countries, but particularly in France, Belgium, Austria and Germany, one hears much of the lack of funds for equipment for teaching and research, both in schools and in hospitals. There is no duobt that much of this is true, since the governments are not in position to make large donations, and since the rich men of these countries and especially the new "war" rich have not yet come to realize their obligation to support education and research. It is possible that the age-long tradition of the maintenance of elaborate estates and luxurious methods of living operate to prevent great private donations for public good, so common in the United States. There, also, the wealthy classes are probably more heavily taxed than in the United States.

---

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 15, 1927.

Too much stress, however, must not be laid on lack of financial resources as retarding medical education and research. There are many places, Vienna for example, in which magnificent work is going on under the most adverse financial conditions. As always, it is the spirit that counts rather than luxurious material equipment.

Increased Trend Toward Medicine of Own Nationals Recently Released from Military Service.—In this country the undergraduate departments of all our universities have been unusually crowded since the war, partly by the return of young soldiers whose schooling was interrupted for two years. In every one of the warring countries in Europe, this condition has even been much more marked than in the United States, since the interruption by the war was more complete and for a much longer period. This crowding has temporarily so overburdened the teaching staffs of the schools with undergraduate work that they possess considerably less time for engaging in research or supervising the work of graduate students.

Flood of Students from Southeastern Europe, Asia and Africa.—Besides the great increase of their own citizens, almost all the older schools of continental Europe are receiving a flood of students from southeastern Europe, western Asia and northern Africa. Everywhere one hears that these students are too frequently without educational background or tradition, without adequate preliminary preparation, and with the desire only to acquire knowledge for purely utilitarian purposes. Almost everywhere they are considered undesirable, and yet in most places it has been almost impossible to formulate rules which would eliminate them. Just after the war, Russian refugees swarmed into the universities of many other countries in such numbers and proved themselves such a disturbing factor that few of them now remain.

National Antipathies Developed by War.—It is doubtful whether there is a university worthy of the name in any European country except Russia in which a serious-minded American medical student would now find himself handicapped by antipathies remaining since the war. I was everywhere impressed by the absence of any such general feeling. There are, of course, individuals who are still unreconciled and tend to blame the Americans for their present condition. Just at present one hears quite a lot, or rather reads quite a lot, concerning the ill feeling of the French for Americans. I am sure this feeling is unusual in medical circles.

FIELDS OF MEDICINE IN EUROPE WITH OPPORTUNITIES FOR SERIOUS STUDY SUPERIOR TO THOSE IN THE UNITED STATES

The time was, and not so long ago, when every American medical student who wished to get the best in almost any special field of medicine was forced to go to Europe for his inspiration and opportunities. For almost every subject that day is gone. Scarcely a single field of medicine remains in which there may not be found in America in at least a few places inspiration and opportunity quite the equal of those in Europe. But in many fields there are not nearly enough research or clinical assistantships available in American medical schools, with adequate teaching staffs and facilities, to supply the widespread demand for more thorough graduate training. And it is, of course, also true that there are many advantages incidental to European scientific study, history, art, music and the drama, which greatly broaden the mind susceptible of being broadened and which are usually lacking or inoperative in the student's own town or medical school in America, however good the local inspiration and material equipment for purely medical graduate study.

Any attempt to compare the opportunities in the several fields of medicine in America with those in Europe must be based largely on individual contacts, which from their very nature are usually inadequate for sweeping judgments. My own observations would suggest that in the fields of physiologic chemistry, anatomy, bacteriology, roentgenology, pediatrics and general surgery there are many opportunities for graduate study in America under inspiring masters and with abundant facilities equal or superior to those in Europe. On the other hand, in pathology, tropical medicine, dermatology, neurology, general internal medicine and orthopedics, the graduate student will find much more extensive and, in some instances, superior opportunities in Europe. Physiology apparently is an even game of high excellence on the two sides of the Atlantic. In the head specialties, the ideals of the students and graduate teachers in both Europe and America all too frequently seem to be centered too much on technic. There are exceptions on both sides of the Atlantic, of course, but altogether too much of the teaching appeals only to the poorest minds entering the medical profession, to men whose sole object is to become sufficiently skilful in as short a time as possible to enable them to make money in the easiest manner.

It may not be amiss to speak further of some of the factors that seem to me to make for superior opportunities in certain fields for graduate study in Europe.

Necropsies.—In the United States there are, perhaps, half a dozen institutions in which the graduate student may have a chance to get his hands into two or more necropsies a day throughout the year. In continental Europe there is scarcely a medical school in which he cannot have an experience as extensive as this. It is a disgrace to American medicine that the intelligent cooperation of the public has not been more widely obtained in permitting examination of the bodies of the dead. At present, dozens of graduate medical students ask every year where they can get adequate opportunity for postmortem service. There are very few places where there is sufficient material under inspiring supervision to warrant a good man spending his time for a year, either as a preparation for pathologic teaching or as a groundwork for clinical medicine or surgery. On the other hand, if he has the funds and can understand German, French or Italian, he can find in Europe any number of places where the material is abundant and the supervision and instruction splendid.

Tropical Medicine.—Doubtless the restricted colonial policy of the United States is greatly responsible for our limited development in tropical medicine. Although, since the Spanish-American War, much interest has developed in the diseases of our tropical colonial possessions, the attitude of most of the medical profession in the United States toward these problems is one of disinterestedness. We tend to think on parallels of latitude rather than meridians of longitude. Our governmental policy has left to private benefaction and to business interests the work in the study and control of tropical diseases, which, in England, Holland and Italy, for example, receive relatively superior governmental support, and which greatly interest the medical profession of these several countries. The serious student of tropical medicine, after exhausting opportunities in the United States, will find an extensive field open to, and still before, him in any of the countries named.

Dermatology.—Why dermatology has been so slow in developing in America is difficult to explain. Certainly it is not from lack of material, as used to be thought. Yet many of the larger cities in the United States are without competent dermatologists, and very few places in the United States provide the graduate student with the opportunity to study more than the mere rudiments of the specialty. In Europe there are many such, probably with Vienna and Paris still leading.

Neurology and Psychiatry.—In America too many of our neurologic and psychiatric institutions are in communities distant from medical-teaching centers, and either by this isolation or by their organization are frequently not utilizable for teaching purposes. In most European countries, the universities absolutely control the teaching facilities in such institutions. The special student of neurology or psychiatry, in most instances, at present cannot well afford to omit European study.

Internal Medicine.—Many of the older great hospitals in America were organized and built exclusively for the care of the patient. Education has been an afterthought. In too many the chief interest of the members of the staff is neither education nor even the care of the hospital patient, but private practice outside the hospital. Medical schools attempting to utilize the clinical material in these hospitals for graduate or undergraduate teaching purposes may often obtain only grudging cooperation on the part of the management and only half-hearted service on the part of the visiting staff. Students are sometimes regarded as a nuisance. The management considers it essential to provide luxurious conveniences, and at the same time to reduce the per capita cost to a minimum. As a consequence, professional service suffers.

Nearly all the great medical hospitals of Europe are as much a part of the university as are the laboratories, and the student is as much at home in them. Patients are well cared for, although with conveniences far from luxurious. The per capita cost is low and the number of beds high. The professor of medicine may have come into his position through extensive laboratory and research training, or he may have come from general practice. It is noteworthy that, whatever may have been his previous experience, almost without exception he sees that the routine care of patients is of a high order, that groups of patients in whose diseases he is at the time especially interested are held for intensive study, and that his assistants, both undergraduate and graduate, are required to make careful investigations, from both the clinical and the laboratory standpoints. There are few places in America where there is such complete control of such a large number of hospital medical cases by one competent head as in any one of many university clinics in continental Europe.

Orthopedics.—The superior anatomic training of the older European surgeons gave them excellent preparation for meeting the tremendous demands in orthopedic surgery incident to the World War. Indeed, it may be that the frequency of European wars has always tended to develop orthopedic surgery more than it would have been otherwise. Certainly, even when one leaves out of account the clinics of the great geniuses in orthopedic surgery, such as Putti of Bologna and Robert Jones of Liverpool, there is still an astonishingly large number of orthopedic clinics throughout Great Britain and continental Europe in which the facilities in material and inspiration are most alluring to the graduate student. This is in marked contrast to most orthopedic centers in the United States, where often the material is deficient, the leadership is lacking, or the organization fails to provide facilities for the graduate student.

TYPES OF GRADUATE STUDENTS

American graduate students of medicine seek in the hospitals, clinics and laboratories of Europe about the same opportunities they seek in America.

Visitors.—By far the largest group of American physicians abroad consists of the more experienced general practitioners, physicians or surgeons who are visiting Europe, usually with their families, during the tourist season, and who plan to spend a few days or occasionally a few weeks in each of several medical centers attending clinics and demonstrations and, when possible, discussing with men, with whose writings they are familiar, topics of clinical or fundamental scientific interest. These visitors are everywhere received with courtesy and given every opportunity they may reasonably expect. But they suffer under a number of handicaps, some of which are unnecessary. For example, they frequently go in the summer and early autumn when university men are tired from teaching or are on their vacations. Medical pilgrimages to Europe should be made between October and May, rather than during the summer months.

Another serious handicap is the visitors' usual inability to understand any foreign languages. It is true that most of the leaders in medicine in continental Europe speak some English, but quite naturally they lecture in their own language, since the bulk of their audiences is composed of students from their own country. Only occasionally clinics and demonstrations are put on in English for the benefit of large groups of traveling Americans. The American physician who expects to get the most out of European travel should at least understand German and be able to ask intelligent questions in that language. He is still better off if he also understands French. Just at present, he will miss excellent opportunities if he does not also have some knowledge of Italian. From my experience with a considerable number of graduates of class A medical colleges during the last decade, I regret to say that the present language requirements of the medical student are almost uniformly failing to train them sufficiently in any foreign language to permit them to utilize it as a means of getting further training abroad. The traveling American physician who understands only English may utilize his time to the best advantage in the clinics of the British Isles.

A further handicap to which the older traveling American physician unnecessarily subjects himself is the neglect to forward proper letters of introduction. The unpleasant memory of the American physicians who thronged Europe from fifteen to thirty years ago, and many of whom were so obviously untrained, still lingers in the minds of the older and more influential medical teachers of Europe. They do realize, however, that any American physician who has a connection with a class A medical school is likely to be better trained They also regard with respect the clinician or laboratory worker who has made some worthy contribution to the literature of his subject A brief and conservative statement of a man's teaching position and of his scientific contributions in a letter of introduction not only orients him properly but insures him a reception which he may not otherwise obtain

Short-Term Students.—The next most numerous class of American medical graduate students in Europe consists of those who desire to be intensively instructed, usually in some limited field, for a relatively brief period, from a few weeks to a few months These men may be already practicing a specialty and wish to have further instruction in that field; they may be general practitioners expecting to confine themselves to a limited specialty, or they may be recent graduates who wish to take work either in a clinical specialty or in some preclinical field preparatory to entering a clinical specialty. Aside from clinics, there are relatively few opportunities for instruction in short-term courses in Europe The most popular, the broadest and perhaps, in general, the best opportunities are to be had in Vienna, although Berlin and Budapest also provide excellent facilities in many subjects There are few such in London except in clinical demonstrations previously mentioned.

I regret to say that some American medical students doing this sort of work abroad are not of the highest type and bring opprobrium on American medical schools. They are apparently ignorant of the fundamentals and seek only easily obtainable certificates It is deplorable that such persons can obtain, with little exertion, certificates of attendance bearing elaborate seals from institutions with world-honored names. These they afterward exhibit in their offices at home as proof to the uninformed public that they are graduates in special fields from great universities. Of course, the American medical profession can do nothing to eliminate them, and unfortunately most of the postgraduate teaching staffs of the European centers that offer brief, intensive postgraduate courses are so anxious for the remuneration for their services that they do not take adequate means to eliminate the unfit. If the universities fostering graduate instruction abroad would adopt more stringent rules, parallel with those of the American Medical Association, concerning the granting of certificates and diplomas, much could be done to eliminate this evil.

In criticizing this class of American medical students abroad one must not forget that they constitute only a relatively small percentage of students, for the bulk of students seeking intensive instruction are really honest and earnest, and fairly well equipped with a general medical training.

Clinical Assistants.—The third group of graduate American medical students going abroad is composed of those who wish to spend a considerable period as clinical assistants. Six months is usually the minimal time for which this opportunity is sought, the year being the much more common unit, while many extend their stay to two or three years. At present, such assistantships are purely voluntary and in some instances indeed are paid for by the student, since the universities do not have the funds to pay even such small stipends to other than their own citizens as they sometimes paid before the war.

In Vienna, Budapest, Berlin and some of the other centers where intensive didactic courses are given, volunteer assistants are sometimes selected by members of the staff from among the paying students taking these courses But the most satisfactory, and in many places the only way volunteer assistantships can be obtained is through previous introduction by some one known to the professor in question, or through the student's home university.

In many places such assistantships in medical fields may be obtained by properly qualified and properly introduced American applicants. In many places they cannot be obtained in general surgery, especially in operative work, since there is usually great pressure from the university's own students who, quite properly, are given priority. Perhaps opportunities to assist in general operative surgery are more open in Budapest than in any of the other centers at present, where this privilege may be obtained for a fee. Assistantships in diagnosis and the nonoperative treatment of general surgical patients may be obtained by competent, well recommended men Excellent and comprehensive experience in orthopedics and all the nonoperative clinical branches may be obtained by similar men in a great many places. The American medical student who wishes to do this sort of work should invariably take care to make his arrangements through some well known man who knows him, or through some university long before starting abroad for such study. Any foreign student dropping in unannounced and unexpectedly on any organization that is doing worth-while work, either in Europe or in America, will almost certainly find himself seriously handicapped for several weeks or months

Research Assistants.—The fourth group of American medical graduate students going abroad is composed of those who wish to engage in special fields of research, usually in the preclinical branches While there is usually no longer any great necessity for American medical graduates to go abroad for opportunities to do laboratory research work because of lack of facilities at home, yet it sometimes happens that some one abroad has made a discovery, perhaps involving a new technic, which is related to work already in progress on this side of the water. In such a case the simplest and the fairest way of checking up results and of getting help in one's own investigations is to obtain permission to work in the laboratory of the European investigator. I am delighted to say that the attitude of secrecy concerning new discoveries and new technic which prevailed years ago, so far as I can discover has, in large measure, disappeared. The capable, earnest and properly recommended American investigator who wishes to work with almost any good man abroad is received with every courtesy and given every facility available. It seems to me that universities both here and abroad might, with great profit, make even many more such interchanges of research assistantships than they do at present. It may be difficult to make clear to governing bodies of universities the value to the institution of sending junior members of its faculty abroad for clinical assistantships in preparation for their teaching, but it ought to be easy to make clear to them the great benefit that might accrue from the interchange of research assistantships.

Exchange Professorships.—This leads me to mention the desirability of more exchange professorships or lectureships in medical subjects. There is a considerable flow of European lecturers to the United States at present and they are doing much good. At the same time one cannot but feel that there is equal need in European universities for American lecturers in certain fields in which American medicine has made outstanding advances, as in certain phases of experimental anatomy (growth), physiologic chemistry (endocrines), physiology (nutrition), pediatrics (child welfare), hygiene (food-handling), general medicine (exophthalmic goiter) and surgery (gastric).

ORGANIZATION

The customs of most European universities are so materially different from those in America that at first the graduate medical student abroad may have considerable difficulty in understanding and complying with them. However, when the graduate student is doing work in a medical science, such as anatomy or chemistry, he can almost always register in the university and receive credit for his work in units of academic years. In some places the semester is the unit.

In most places graduate work in clinical branches is done under very loose university control, and no attempt is made to give university credit. The prospective student simply selects the man with whom he wishes to work and makes personal application to him; the university may or may not know anything about the student. In Vienna, Berlin and Budapest, there are university departments or committees through which graduate-student organizations work in the arrangement of courses, the regulation of fees and the granting of certificates. The medical student associations of these places may render valuable service to the prospective graduate student in medicine from America, and certainly should be consulted by every one going for the first time to any one of these places. It should be remembered, however, that they are concerned almost entirely with the arrangement of intensive courses of instruction and are seldom able to give much help in securing clinical assistantships or opportunities for research.

In London the Fellowship in Medicine serves as an admirable information bureau and central registration point for the clinical worker in that city. The Fellowship is also extending its information and registration service to cover similar opportunities in other cities of the British Isles. Here again, however, the service rendered is chiefly of interest to the visitor or short-term student who desires to visit clinics and hear lectures. If one wishes to do more than this, he must make arrangements personally with the professor with whom he wishes to work.

The American University Union in London and in Paris is able to give valuable information concerning opportunities for graduate work in medicine. Its offices in both cities also provide central meeting points for Americans studying there.

In general, it may be said that if the American physician wishes to spend time in Europe visiting clinics, listening to lectures or taking brief intensive courses, he cannot do better than seek information from the agencies mentioned. But if he wishes to spend a considerable period, a year or more, actually working either in the laboratory or in hospital wards, he should make his arrangements with the professor with whom he wishes to work. He usually can do this most satisfactorily through the American university with which he is connected.

EUROPEAN CLINICS PROVIDING GOOD OPPORTUNITIES FOR AMERICAN MEDICAL GRADUATE STUDY

It is, of course, impossible with the limited information at hand to list all the good places where one may do graduate medical work abroad under satisfactory conditions. Even if such a list were complete it would be good at most for only one year, since changes are constantly occurring. However, since such a list has not been published recently it may not be amiss to append one to this article. The institutions are only those of which I have personal knowledge or which have been recommended to me personally on reliable information through American sources. The list is in no sense complete. Indeed, I suspect that some of the best opportunities for work available in Europe are not included, but unfortunately I have no accurate information concerning them.

LIST BY CITIES

Places starred are known to give short clinical or laboratory courses.

Amsterdam.—University of Amsterdam, Amsterdam, Netherlands. For information concerning clinical and research assistantships, address the professor in charge of the department and also the dean of the faculty of medicine. A new building of the Colonial Institute houses the Institute of Hygiene (Tropical Medicine) of the university. Prof. W. M. deVries, head of the department of pathologic anatomy, and Prof. B. Brouwer, head of the department of neurology, visited the United States in 1926.

Barcelona.—University of Barcelona, Barcelona, Spain. Properly qualified American graduates may be given opportunity to work in medicine, physiology or pathology. For information, address the dean of the faculty of medicine, University of Barcelona, Barcelona, Spain.

**Berlin.*—Medizinische Fakultät der Friedrich-Wilhelms-Universität. For information concerning short courses, address Director of Kaiserin Friedrich-Haus for postgraduate medical education, Berlin, N. W. 6, Luisenplatz, 2-4 Kaiserin Friedrich-Haus.

For clinical and research assistantships, address the professor in charge of the department and also the dean of the faculty of medicine of the university.

Valuable assistance concerning courses and facilities of students, academic procedures, and so forth, may be obtained from Amerika-Institut, Berlin, N. W. 7, Universität Str. 8, Berlin, Germany.

Berne.—Kantonale Universität, Berne, Switzerland. For information concerning clinical and research assistantships, address the professor in charge of the department and also the dean of the faculty of medicine.

Professor Asher, director of the institute of physiology, has recently visited the United States.

**Birmingham.*—University of Birmingham, Birmingham, England. For information concerning demonstrations and lectures, address W. F. Haslop, Esq., M.B., F.R.C.S., the University, Edmund Street, Birmingham, England.

Bologna.—University of Bologna, Bologna, Italy. For information concerning clinical and research assistantships, address the professor in charge of the department and also the dean of the faculty of medicine.

The Institute Rizzoli, under the direction of Professor Putti, is a wonderfully complete institute for orthopedic patients. Professor Putti recently visited the United States.

**Bordeaux.*—University of Bordeaux, Bordeaux, France. For information concerning special courses, apply to Dr. Leon Felderman, 4428 York Road, Philadelphia, Pa.

**Bristol.*—University of Bristol, Bristol, England. For information concerning clinical assistantships in special branches of hospital practice, address the director of postgraduate studies, Pathologic Department, University of Bristol, Bristol, England.

Brussels.—University of Brussels, Brussels, Belgium. For information concerning clinical and research assistantships, address the president of the faculty of medicine of the university.

Prof. P. Vandervelde, president of the faculty of medicine, Prof. A. Slosse, director of the physiologic institute, and Dr. Pierre Depage have recently visited the United States.

**Budapest.*—An "Official Guide of Postgraduate Work in Hungary for English Speaking Physicians" is issued annually conjointly by the Hungarian Postgraduate Medical Committee and the American Medical Association of Budapest, and may be obtained from the Royal Hungarian University Press of Budapest.

**Cambridge.*—University of Cambridge, Addenbrooke's Hospital. For information concerning demonstrations, write Dr. J. Alden Wright, 54 Trumpington Street, Cambridge, England.

For information concerning opportunities for research, address the registry of the University, Cambridge, England.

Copenhagen.—University of Copenhagen, Denmark. For information concerning clinical and research assistantships, address the dean of the faculty of medicine.

Prof. August Krogh, head of the department of physiology, and Prof. Knud Faber, head of the department of internal medicine, have recently visited the United States.

Dublin.—University of Dublin, Dublin, Ireland. A diploma in gynecology and obstetrics may be granted registered medical practitioners with six months' residence at the Rotunda Hospital and six months' study at Trinity College. Three months of the latter may be coincident with the hospital residence. A similar diploma in psychologic medicine may be granted also.

For information, address the dean of the faculty, School of Physic, University of Dublin (Trinity College), Dublin, Ireland.

**Edinburgh.*—University of Edinburgh, Edinburgh, Scotland. For information concerning courses, address the secretary of postgraduate courses in medicine, University New Buildings, Edinburgh, Scotland.

Opportunities for unofficial clinical and research work should be arranged with various departments. Address applications and inquiries to the dean of the faculty of medicine, University New Buildings, Edinburgh, Scotland.

Sir Norman Walker, secretary of the Royal College of Physicians of Edinburgh, Sir Harold Stiles, emeritus professor of surgery, and Mr. D. P. D. Wilkie, professor of surgery, have recently visited the United States.

Florence (Firenze).—University of Florence, Florence, Italy. For information concerning clinical and research assistantships, address the professor in charge of the department and also the dean of the faculty of medicine and surgery.

Genoa.—University of Genoa, Genoa, Italy. For information concerning clinical and research assistantships, address the professor in charge of the department and also the dean of the faculty of medicine and surgery. (About half of a large number of magnificent new buildings for the university and city hospital were completed in 1926.)

Cav. Dott. Luigi Durante of the department of surgery was a student in the United States in 1915.

**Glasgow.*—University of Glasgow, Glasgow, Scotland. Postgraduate courses summer months (June to October): general medical and surgical courses, special clinical courses, clinical assistantships. Winter months: demonstrations in medicine, surgery, obstetrics, ophthalmology. Address the secretary, Glasgow Postgraduate Medical Association, University, Glasgow, Scotland.

For information concerning clinical and research assistantships, address the professor in charge of the department and the dean of the faculty of medicine.

Mr. Archibald Young, professor of surgery, visited the United States in 1926. Dr. J. R. Learmonth of the department of surgery was a student in the United States in 1924 and 1925.

Hague.—Visitors interested in surgery should seek appointment in advance with Dr. Jan Shoemaker, Gemeente-Ziekenhuis, Zuidwal 83, The Hague, Netherlands. Dr. Shoemaker has visited in the United States.

Lausanne.—University of Lausanne, Lausanne, Switzerland. For information concerning opportunities to work in laboratories or hospitals, address Prof. F. Genin, dean of the faculty of medicine, University of Lausanne, Lausanne, Switzerland.

Leeds.—University of Leeds, Leeds, England. For information concerning clinical and research assistantships, address the professor in charge of the department and the dean of the faculty of medicine.

Sir Berkeley G. A. Moynihan, professor of clinical surgery, has frequently visited the United States.

Leiden.—University of Leiden, Leiden, Netherlands. For information concerning clinical and research assistantships, address the professor in charge of the department and also the dean of the faculty of medicine.

Prof. William Einthoven, director of the institute of physiology, recently visited the United States.

Leipzig.—University of Leipzig, Leipzig, Germany. For information, address the director of the institute where it is desired to work or the dean of the faculty of medicine, University of Leipzig, Leipzig, Germany.

Liverpool.—University of Liverpool, Liverpool, England. The mastership of orthopedic surgery is open to graduates of approved universities. The diploma in medicine, radiology and electrology, and the diploma in public health are open to graduates holding qualifications registered by the General Medical Council of Great Britain The mastership of hygiene and also the diplomas in tropical medicine and tropical hygiene are open to graduates of approved universities. The degree of doctor of philosophy may be conferred for two years' research in the department of biochemistry, bacteriology, physiology, or entomology on graduates of the university and colleges included in the list issued under the authority of the Association of American Universities of 1917 For detailed information apply to Mr Walter J Dilling dean of the medical faculty, University of Liverpool, Liverpool, England The application should be supported by a letter of recommendation from the applicant's dean of the faculty

*_London_ —University of London, London, England For detailed information concerning lecture courses and demonstration courses, apply to the Fellowship of Medicine and Postgraduate Medical Association, No 1, Wimpole Street, London, W 1, England

For clinical or research assistantships apply directly to the several schools, or of those in the University of London apply to Mr Edwin Deller academic registrar, University of London, South Kensington, London, S W 7

American University Union, 50 Russel Square London, W C. 1, England

Mr Deller, Mr W Sampson Handley professor of surgery at Middlesex Hospital Dr A V Hill, professor of physiology, University of London, and Dr Archibald Leitch, director of the Cancer Hospital Research Institute, visited the United States in 1926

*_Manchester_ —Royal Infirmary Manchester, England For information concerning clinical lectures and demonstrations given each autumn and spring, write to E Bosdin Leech, M D, 16 St John s Street, Manchester England

Milan —University of Milan, Milan Italy For information concerning clinical and research assistantships, address the dean of the faculty of medicine The university buildings are all new and modern

Montpellier —University of Montpellier Montpellier, France Foreign students not applicants for degrees or diplomas are admitted on presentation of satisfactory evidence that they can follow the teaching of the faculty For information, address the secretary of the faculty of medicine, University of Montpellier, Montpellier, France

Munich —Ludwig Maximilians Universität, Munchen Properly qualified graduates of good character and with sufficient knowledge of German may be received as clinical or laboratory assistants when facilities permit Application should be made to the head of the clinic or laboratory with whom work is desired and also to the secretary of the university

Professor Friedrich Muller, professor of medicine, visited the United States in 1926

Padua —University of Padua, Padua Italy For information concerning clinical and research assistantships, address the rector of the University of Padua The present rector is Professor Luigi Lucatello, professor of medicine

*_Paris_ —University of Paris Paris France For all information concerning clinics, hospitals, postgraduate courses and clinical and research assistantships address the dean of the faculty of medicine 12, Rue de L Ecole de medecine, Paris (IVe)

For general information, address American University Union, Continental Division, 173 Boulevarde Saint Germain Paris, France

Prof Edouard Rist, in internal medicine, and Prof J E Forrestier, in roentgenology, visited the United States in 1926

Prague (Praha, Cechoslovakei) —Charles University (Czech) For information concerning clinical and research assistantships, address the dean of the medical faculty

Deutsche Universitat (German) For information concerning clinical and research assistantships, address the secretary of the medical faculty of the German university

Prof Arthur Biedl of the department of experimental pathology, Deutsche Universitat, visited the United States in 1923

Rome —Royal University, Rome, Italy For information concerning clinical and research assistantships, address the director in charge of the department and also the dean of the faculty of medicine and surgery

Prof Roberto Allessandri and Prof Raffale Bastianelli of the department of surgery visited the United States in 1926

St Andrews —The James McKenzie Institute for Clinical Research, St Andrew's, Scotland For information concerning courses for general practitioners, write Dr J Hunter Paton, secretary.

*_Sheffield_ —University of Sheffield, Sheffield, England For information concerning clinical lectures and demonstrations, write to the Honorable Secretary, Committee of Clinical Studies, University, Sheffield, England

Stockholm —Karolinska Medico Kirurgiska Institut For information concerning clinical and research assistantships, address the dean of the faculty

Prof H C Jacobaeus, head of the department of internal medicine, visited the United States in 1926

Strasbourg —University of Strasbourg, Strasbourg, France Properly qualified American graduates are cordially welcome in clinical services and scientific departments For details, address the dean of the faculty of medicine, University of Strasbourg, Strasbourg, France.

Utrecht —Rijks Universiteit, University of Utrecht, Utrecht, Netherlands For information concerning clinical and research assistantships, address the director of the faculty of medicine

Prof R Magnus, director of the pharmacologic institute, visited the United States in 1926

*_Vienna_ —Postgraduate courses are in progress continually throughout the year except during the months of July, August and September, when the number of courses is reduced because of staff vacations. Detailed information is given in the Blue Book of the American Medical Association of Vienna Address the secretary of the American Medical Association, viii, Alserstrasse 9, Vienna, Austria Hungary.

The best method for obtaining assistantships is directly with the professor concerned Prof Karl F Wenckebach, head of the first clinic in internal medicine; Prof Ernst Fuchs of the department of ophthalmology, Dr Oskar Frankl of the department of gynecology, and Dr A Schuller of the department of neurology, have recently visited the United States

Warsaw —University of Warsaw, Warsaw, Poland. American graduates from medical schools of equal standing with those of Poland may be received as volunteer assistants for any length of time after obtaining permission from the directors of the hospitals or departments of the Warsaw medical school in which they may wish to work Detailed information may be obtained directly from these or from the dean of the faculty of medicine, University of Warsaw, Warsaw, Poland, or through Prof Dr. G Modrakowski, dean of the faculty of medicine

Zurich —University of Zurich, Zurich, Switzerland For information concerning clinical and research assistantships, address the professor in charge of the department and also the rector of the university

Prof Felix Nager of the department of otolaryngology visited the United States in 1926

MEDICAL PRACTICE IN CUBA

ADDRESS OF DR. J. M. PENICHET, DELEGATE OF THE CUBAN FEDERATION OF PHYSICIANS TO THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION

I wish to thank the President, officers and members of the American Medical Association for the honor that has been conferred on the Cuban Federation of Physicians, inviting our institution to participate in this annual reunion.

I also wish to express my personal thanks for your kind reception. First of all I bring a message of friendship to the members of the American Medical Association from the three thousand physicians of my country. Our executive committee has sent me to Washington, and I am here to explain to you what we are, what we have been doing, and what we hope to do in the future. Perhaps a better knowledge of our present conditions will help to enlarge the field of mental speculations or of practical adaptations along the lines of ideals that we pursue.

I know that this cannot be accomplished in a day, but somehow I feel that you will recognize the importance and the purity of principles of our cause.

The medical profession in Cuba has had three very interesting periods in its evolution. The one before the War of Independence, the one during the war, and the one subsequent to the establishment of the republic.

I will not go into details, but before the War of Independence the practice of medicine was absolutely free. Each physician had his own patients. He was honored and respected by the family. He was able to make and save enough money to live well and to protect himself in his old age. During the war these physicians were the first to sacrifice the comforts and pleasures of life. Giving up everything they had, a large number of them died for their country. This war was called the physicians' war, and that age can be named the romantic age.

Things have changed. At the present moment, and unless our efforts lead us to a final victory, the practice of our noble profession in Cuba will be almost impossible.

I will try to prove my assertion.

Our population is, according to our last census, a little over 3,000,000 inhabitants. There are more native whites than negroes, but the foreigners, especially the Spaniards, represent just about half of the former. We have 3,000 physicians practicing in the island, and they are Cubans by a large majority. If things were such as they should be, we would have an average of a thousand persons to every physician. Supposing that only 10 per cent of this number should be in need of our services, then we would have an average of a hundred patients to every physician. But this is not so. There are 666 individuals out of a thousand who belong to the great Spanish societies for the protection of health. This leaves 334 probable patients. Supposing 10 per cent of this number have need for medical services, we have really only thirty-four to depend on.

About fifty years ago the Spaniards, in order to protect their immigrants, established a type of society which in the beginning answered the purposes for which it was created, the medical attention of the laboring class. But right from the start the patrons took command of the board of directors and soon afterward they also joined in the privileges of their employees. In a very few years a number of other societies were founded, as many as there are provinces in Spain. For the small amount of $2 a month any member is entitled to the services of a specialist, and in case that his condition should require hospitalization, he will have at his disposal the very best equipped in the country. Besides, he can get a certain form of preliminary instruction and his family may participate in the different courses in music, painting and sculpture. If he is a sociable man, his club is ready to receive him and there he will find, among the luxuries of these magnificent buildings, every possible sort of entertainment. If he does not care to deal with our national or foreign banks, he has a bank of his own. If he goes to moving pictures or to the theater, he has every opportunity in the world to please himself.

This would be an ideal conception for the laboring class; but the rich, the very rich, belong just as well to these societies. The highest representatives of the banking business, commerce, industry, government and politics are the principal associates of these institutions.

And it may surprise you to know that all the money comes out of their hospitals. Cuban physicians work day and night; they very seldom take a vacation—perhaps just a few of the lucky ones may do so—and the salary they get is something ridiculous. That is why we have founded the Cuban Federation of Physicians, to fight against these powerful trusts and free the medical profession. We have had already two strikes which we have lost, but we keep on fighting for the justice of our cause.

There are other things which we are dealing with. We are trying to raise the morals of our class. We are in contact with our national university, high schools, and private ones so that the efficiency of all of them shall come up to the standard of the best in the world. We are doing away with quacks and every other representative of medical fraud. We are trying to pass a number of laws in our congress, among them laws regulating the practice of optometry; in a word, we are doing as much as we can for the benefit of the public and that of the medical profession.

Gentlemen, friends, we are today celebrating a mass meeting in the city of Havana. It will be like a ray of sunshine, a stimulant which will make our hearts beat with joy, if you, members of the American Medical Association, would send a cable to the Cuban Federation of Physicians, just saying that on this side of the world, in this wonderful country of Washington and Lincoln, there are minds and souls capable of understanding us and ready to uphold our ideals, which after all are the ideals of the great medical family.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

POLLEN EXTRACTS-CUTTER (See New and Nonofficial Remedies, 1927, p. 34).

Pollen extracts-Cutter are now marketed as follows: in capillary tubes for diagnostic tests; in complete treatment set packages consisting of three vials representing graduated concentrations: 1 in 10,000, 1 in 1,000 and 1 in 100, respectively.

The following additional products have been accepted:

Alkali Weed Pollen Extract-Cutter; All Scale Pollen Extract-Cutter; Box Elder Pollen Extract-Cutter; Burning Bush Pollen Extract-Cutter; Corn Pollen Extract-Cutter; Foxtail Pollen Extract-Cutter; Mountain Cedar Pollen Extract-Cutter; Tumbleweed Pollen Extract-Cutter; Western Water Hemp Pollen Extract-Cutter.

POLLEN EXTRACTS (GLYCERO-SALINE)-MULFORD.—Liquids obtained by extracting the dried pollen of plants with a liquid consisting of 66⅔ per cent of glycerin and 33⅓ per cent of saturated sodium chloride solution.

Actions and Uses.—See Allergic Protein Preparations, New and Nonofficial Remedies, 1927, p. 23.

Dosage.—See Allergic Protein Preparations, New and Nonofficial Remedies, 1927, p. 23.

Pollen extracts (glycero-saline)-Mulford are marketed in bulk treatment packages consisting of one vial containing 1 cc. of the glycero-saline pollen extract and two 10 cc. vials of physiological solution of sodium chloride containing 0.5 per cent of phenol for making dilutions, and in treatment sets consisting of:

First series: five vials (doses 1 to 5, inclusive) containing, respectively, 25 protein units, 50 protein units, 75 protein units, 100 protein units and 150 protein units, accompanied by five vials of sterile distilled water containing 0.5 per cent of phenol.

Second series: five vials (doses 6 to 10, inclusive) containing, respectively, 200 protein units, 250 protein units, 375 protein units, 500 protein units and 625 protein units, accompanied by five vials of sterile distilled water containing 0.5 per cent of phenol.

Third series: five vials (doses 11 to 15, inclusive) containing, respectively, 750 protein units, 875 protein units, 1,000 protein units, 1,125 protein units and 1,250 protein units, accompanied by five vials of sterile distilled water containing 0.5 per cent of phenol.

Complete series: fifteen vials containing doses 1 to 15 inclusive, described in the First, Second and Third series, accompanied by fifteen vials of sterile distilled water containing 0.5 per cent of phenol.

Fourth series: five vials (doses 16 to 20, inclusive) each containing 1,250 protein units, accompanied by five vials of sterile distilled water containing 0.5 per cent of phenol.

Lamb's Quarters Pollen Extract (Glycero-Saline)-Mulford; Ragweed Pollen Extract (Glycero-Saline)-Mulford; Timothy Pollen Extract (Glycero-Saline)-Mulford; Wormwood Pollen Extract (Glycero-Saline)-Mulford.

Manufactured by the H. K. Mulford Company, Philadelphia. No U. S. patent or trademark.

A solution containing 66⅔ per cent of glycerin and 33⅓ per cent of saturated sodium chloride solution is thoroughly mixed with the pollen in a quantity to make a 10 per cent pollen suspension. The mixture is agitated occasionally for about seven days, after which the solid residue is removed by filtration. Each cubic centimeter represents the substances extracted from 0.1 Gm. of pollen (100,000 pollen units, approximately equivalent to 25,000 protein units).

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

SATURDAY, JUNE 11 1927

EDUCATION OF THE PUBLIC IN MEDICINE

At the session of the American Medical Association in Washington, the House of Delegates considered carefully the question of education of the public in matters of medicine and of health. It was recognized that such education is desirable for the good of the public and that it aids the medical profession by securing intelligent cooperation in the control of disease both in the individual and among the public. On the other hand, it was also recognized that the publication of articles on health subjects may serve unduly to advertise an individual and that the articles may reflect individual views, rather than well established scientific fact or the views of physicians as a group. Some system of control seems to be needed, particularly at present when the entire matter is in process of development. The House of Delegates concluded that interviews or articles of an educational nature on medical or health subjects, intended for the lay press or lay audiences, should give expression to the consensus of opinion of the medical profession rather than to personal views which may be in conflict therewith, and that articles should appear preferably under the auspices of the American Medical Association or one of its component societies or constituent associations.

In the matter of education of the public regarding the structure of the human body or its functions in health or of the changes that occur in the human tissues and in the functions in disease, there is seldom occasion for difference of opinion. When differences of opinion do arise, they concern matters not well established, or questions of the economic status of the medical profession or its public policy.

There are today at least fifteen individual physicians conducting health columns for the education of the public. Most of these proffer sound advice; occasionally, a column will be devoted to the promotion of a proprietary product in which the conductor seems to have become unduly interested; sometimes to a peculiar notion as to what constitutes good exercise, as for example the somersaulting mania of one columnist; sometimes to the promotion of too rigorous diets in connection with the idea that obesity is a menace to longevity, and sometimes to the strange notion that disease is entirely a matter of the infecting organism and the individual's natural immunity, and that factors which may lessen his natural immunity have little or nothing to do with the case. The instances mentioned are specific, reflecting material that has appeared in some of these individual health columns in recent weeks.

It would be well for all physicians who write on health subjects to bear the conclusions of the House of Delegates in mind. Sufficient accurate information is available, of which the public is as yet uninformed, to offer material for years to come, at least until the knowledge of the average man relative to the human body and its functions shall have caught up approximately with that of the intelligent man of today. In the meantime, discussions of new discoveries, of proprietary products and of special notions may well be confined to medical periodicals, which constitute an open forum for determining the actual status of things in dispute.

THE SYNTHESIS OF THYROXIN

Modern knowledge of the function of the thyroid may be said to date from the observations of Gull in 1873 and of Ord in 1878 on the disease now known as myxedema, and the observations of Kocher and Reverdin in 1882 on what is sometimes designated as cachexia thyreopriva. In 1891 Murray showed the marked curative effect of so-called thyroid extracts in myxedema, and this fact was independently confirmed by Mackenzie in 1892 and by Fox in the same year. A few years later Magnus-Levy showed that there is a reduced heat production in myxedema, and that thyroid therapy gradually raises the oxidative processes to the normal or above it.[1] An event in the study of the thyroid was the discovery of iodine as a constituent of the gland by Baumann in 1895. This was soon followed by the demonstration that certain chemical “fragments” of the tissue retained the therapeutic potency of thyroid extract. Thyroglobulins were shown to be both active and iodine-containing. Thyroiodin, or iodothyrin, was prepared by disintegration of thyroid glands with strong acid and found to be potent.

Chemical evidence that iodothyrin is not a single substance was secured by the isolation in pure crystalline form of a compound containing 65 per cent of iodine. This brilliant success resulted in 1914 from the work of E. C. Kendall, who named the new thyroid derivative thyroxin. The preparation of thyroxin was highly important from the therapeutic standpoint because it has proved to be enormously potent as a stimulant of metabolism, can be used in accurate dosage, and is administered effectively by the intravenous route. A few milligrams produced pronounced and prolonged effects on an adult. The isolation of a well defined chemical substance further justified the hope of a possible production of the compound by artificial synthesis in the laboratory.

---

[1] A review of the physiology, pharmacology and therapy of the thyroid will be found in a series of articles on Glandular Therapy, prepared under the auspices of the Council on Pharmacy and Chemistry of the American Medical Association, and issued in book form.

The announcement by Harington,[2] in 1926, that thyroxin, instead of being a compound of tryptophan as was earlier assumed, is a tetraiodo derivative of the *p*-hydroxyphenyl ether of tyrosine, has been followed by a determination of the orientation of the iodine atoms in the molecule. The chemical structure of the substance is at length clearly established. The crowning achievement is the artificial synthesis of thyroxin by Harington and Barger[3] of London and Edinburgh, respectively. D. Murray Lyon of the University of Edinburgh has made clinical tests of the synthetic product on myxedematous patients which afford a physiologic confirmation of the identity of the synthetic product with natural thyroxin. Thus, on the verge of the centennial of Wöhler's classic synthesis of urea, the first artificial production of a naturally occurring biologic product, the active principle of the thyroid gland has been made available artificially through the chemist's genius for the service of mankind.

THE QUARTERLY CUMULATIVE INDEX MEDICUS

Simultaneously with the opening of the Annual Session of the American Medical Association in Washington appeared the first number of the new *Quarterly Cumulative Index Medicus*, a combination of the *Index Medicus* published by the Army Medical Library with the aid of a grant from the Carnegie Institution, and the *Quarterly Cumulative Index to Current Medical Literature* published by the American Medical Association since 1916. The combination has been welcomed by librarians, by editors, by research workers—indeed, by all interested in medical progress, as a great achievement in the field of medical bibliography. There are published in the world today somewhere between 1,800 and 2,000 medical periodicals. In these appear the fruits of medical investigation in the laboratory, of bedside observations in the hospital and in the clinic, of theories and philosophy developed in the office and in the library. Original articles alone comprise approximately 50,000 titles annually. Many of the articles concern more than one subject, so that they are necessarily indexed under more than one heading. Moreover, the interrelationships of subjects and overlapping may make necessary numerous cross-references. The index is planned to make the location of this material as simple a matter as possible in order to aid all those wishing to refer to the knowledge of the past and to lead the way to new knowledge in the future.

In an address at the dedication of the School of Medicine and Dentistry of the University of Rochester in October, 1926, Dr. John C. Merriam, director of the Carnegie Institution in Washington, traced the manner in which medicine is affected by the evolution of society. Changes in social organization are of direct importance in relation to the practice of medicine. The same subject was discussed almost a hundred years ago by Dr. Oliver Wendell Holmes in an address before the Massachusetts State Medical Society. Science is fact, but medicine is both an art and a science. As such it is inevitably influenced by the social organization of the community in which it develops. Society is continually changing, and in these modern times so rapidly that the changes are easily apparent in a single generation. Any prospect as to the future is obviously dependent on the knowledge of the steps by which man came to his present estate. Dr. Merriam lists six factors on which the advancement of society depends. First, the securing of new knowledge by discovery, invention and research; second, unification of knowledge and the understanding of the interrelation of its parts; third, the development of adequate means for establishing continuity in knowledge; fourth, the physical and mental effectiveness of the individual; fifth, continued betterment of economic and political organization, and, sixth, enlargement of the fundamental or basic capacity of the individual.

The development of the *Quarterly Cumulative Index Medicus* is a step toward the development of adequate means for establishing continuity in knowledge, so that the discoveries of one generation may be transmitted to the next. If the lessons of the present were to disappear with the present, civilization would break down and the next generation would have to begin anew to learn the facts that are already known. A vast amount of unproductive research results from failure to realize the things that have already been demonstrated. So great is the scope of medical literature of the present that the research worker of the future will find the background for most of his problems already laid in writings of the past and of the present.

The *Quarterly Cumulative Index Medicus* is a means for the systematization of medical knowledge. One of the great problems of the future is to simplify still further the carrying of this knowledge to the average physician, so that he may readily avail himself of the best knowledge on any subject. A means for giving to the majority of mankind such of this knowledge as is important for the building of health and the building of better men and women is an ultimate goal.

THE "PHOSPHOCREATINE" OF MUSCLE

The study of the function of muscle has experienced many vicissitudes during the past century. This is due in part to the inevitable circumstance that our knowledge of certain fundamental processes associated with the phenomena of contraction has been of slow development. Thus, without a better understanding of the underlying principles of energy transformation, the dynamics of muscular performance could not be adequately interpreted. In part, progress has been delayed by the changing interests that diverted the minds of investigators from one aspect to another. At one time metabolism and the related phenomena have been regarded primarily from the energetic standpoint; at another, more purely chemical considerations have held sway. A recent writer has remarked that of late years the latter have come more to the front as a reaction against the partiality of which the defenders of the purely energetic or caloric theory of metabolism had been guilty. In commenting on the circumstance that the problem of the activity of muscle has accompanied physiology from its cradle, so to speak, the Nobel laureate Meyerhof[1] pointed out that, in the muscle, nature has produced a machine so startling and at the same time so perfect that the explanation of its mechanism could not only give satisfaction to the searching mind but also promise a rich harvest to the technical progress of mankind. And this problem is so clearly a physical one that even the vitalist admits the possibility of its being solved by means of inorganic natural science, for it is nothing else but the question how chemical energy in the animal body is transformed into mechanical work. Meyerhof has also reminded us that, by studying the muscle exclusively from its physical qualities, it has been overlooked that we have to do with a chemodynamic machine. The comprehension of the mechanism could therefore be arrived at only by the combined efforts of chemistry, energetics and physics. On the other hand, the biochemist who analyzed only the dead material was helpless in view of the progress of dynamics. Thus, Meyerhof added, experimental analysis stagnated, going round in a circle, and all the theories of muscular function were condemned to fruitless speculation.

On various occasions attention has been called to the newer contributions to the physiology of muscle.[2] They have served to throw new light on the rôle of glycogen and lactic acid, substances long identified in vague ways with the workings of the muscles. The oft discussed phosphate of muscle has likewise been linked up of late with sugar in the process by which the lactic acid is evolved. An analogy has been found in the demonstrable occurrence of hexose-phosphate in the process of fermentation of sugar. Indeed, it has been alleged that phosphate plays a very important part in the "respiration" of muscle.

Among the nitrogenous components of the contractile tissue, creatine has long been recognized as conspicuous. Calculations indicate that the adult human body contains an average of about 100 Gm. of this characteristic substance, of which 98 per cent is present in the muscles. Its origin, its function and its fate have long been shrouded in mystery; and this is scarcely less true of the closely related blood and urinary component creatinine. A real step in advance is marked by the recent announcement by Fiske and Subbarow[3] from the Medical School of Harvard University regarding the existence of a "phosphocreatine" in muscle. It appears that the tissue ordinarily contains a form of "labile" phosphorus which may be converted into inorganic phosphate when a muscle is stimulated. A period of rest thereafter is attended by a resynthesis of the organic compound. Whenever the content of this "labile" phosphorus compound diminishes, creatine is set free. This remarkable association of creatine with phosphate and the dissociation incident to functional changes presents an entirely new and unsuspected behavior of a compound long puzzling to the student of muscle chemistry. Creatine evidently is not merely an inert substance that chance has placed in the most active tissue of the body.

Current Comment

THE NEW AMERICAN MEDICAL DIRECTORY

The tenth edition of the American Medical Directory has just been completed, and copies are now available for general distribution. More and more this volume is becoming of importance as a source book of statistics on the medical profession and its allied interests. It provides up-to-date biographic data on the 164,002 listed physicians of the United States, its dependencies, and Canada. A study of the present edition of the directory in connection with previous editions yields some interesting statistical data concerning trends in medical practice. During the past ten years a marked decrease in the number of physicians listed in Arkansas, Iowa, Indiana, Kentucky, Missouri, Indiana and Vermont has occurred. On the other hand, California, Florida, Illinois, Massachusetts, Michigan, Minnesota, New Jersey, New York, Ohio and Washington have shown considerable increases. The new directory contains 10,353 names that did not appear previously; 6,052 names have been omitted since the last directory, these physicians having been reported as deceased. The changes of address during the two year period amounted to 60,029, an average of eighty-two every day. If account is taken of the changes in membership in state medical societies, Fellowship in the American Medical Association, specialties, office hours, teaching positions, and so on, the total number of revisions made in compiling this new edition of the directory reaches an almost staggering figure. One of the new features of the directory is a list of licentiates of the American Board of Examiners, the American Board for Ophthalmic Examinations and the American Board of Otolaryngology. There is also a list of the 145 clinical laboratories included by the Council on Medical Education and Hospitals. The hospitals listed in this edition total 7,816; for each institution the name, location, number of beds, name of medical director or superintendent, and kind of patients handled are provided. The tenth edition of the directory contains 2,575 pages. While its compilation has been a tremendous task, the work has been made much easier by the splendid cooperation rendered by individual physicians, secretaries of various licensing boards, medical colleges and societies and many others who have readily and willingly assisted in furnishing data.

DIABETIC FOODS

A recent food inspection decision of the U. S. Department of Agriculture revokes the official definition of so-called diabetic foods, thus automatically placing such preparations in the class of drugs. The government holds that references to any disease condition in the labeling of such articles implies to the public that they are efficacious treatments, and it therefore asks manufacturers and distributors to eliminate any such references from their trade packages. An investigation showed that "diabetic foods" were being held out to sufferers from diabetes as treatments for their condition rather than as mere dietetic aids in the management of the disease. The action taken is gratifying official support of the effort of the Council on Pharmacy and Chemistry to convince manufacturers that therapeutic recommendations do not have a place on a trade package. In view of the increasing amount of popular instruction that is being given in sound principles of hygiene and preventive medicine, however, the Council has taken a liberal attitude in regard to the advertising to the public of certain kinds of medical preparations. Thus, the Council does not oppose the naming of diseases on trade packages of foods not advertised as curative agents. In passing on a food prepared for use in the diet of diabetics, therefore, the Council does not object to the name of the disease on the trade package, or to a name implying the use of the product in diabetes, provided the advertising put out by the manufacturer makes it clear that the product is not offered as a cure or even as a remedy for the disease. The person who has diabetes and knows it is likely to know also the object and value of a low carbohydrate diet. Indeed, the goal of the best therapy in this disease is the attainment by the patient of ability to regulate his diet intelligently and thus materially to assist the physician in the management of the disease. The greater stringency of the attitude of the government department arises, no doubt, from the fact that it is acting on the basis of a law, the letter of which refers only to the trade package and label. The general application of the new policy will probably not work injustice to any worth-while product. The public should be protected against fraudulent claims of composition, and the department has control over this in any case in which fraud may be shown. Physicians may well confine their recommendations to the products listed in New and Nonofficial Remedies. For these, the claims of composition as well as of therapeutic efficacy have been considered by the Council on Pharmacy and Chemistry.

DIHYDROXYACETONE AND DIABETES

From a quantitative standpoint the carbohydrates represent our most important foodstuff. For this reason, among others, any impairment in the normal catabolism of carbohydrate in the body—any failure to utilize the energy of carbohydrate with the usual facility—represents detriment to the organism. Such a breakdown in the physiologic facilities of the body occurs in diabetes. If the details of the process by which glycogen and glucose, the physiologic carbohydrates, are rendered available in functional performance were precisely known it might be possible to avert or offset defects in carbohydrate metabolism. For example, it has often been assumed that the conspicuous defect in the diabetic condition lies in an inability to convert glucose into the intermediary products which then undergo further metabolic breakdown. Glucose thus heaps up in the blood, not merely because it is formed in undue amounts but because it cannot be started on the regular road of gradual catabolic destruction. Accordingly, if the normal intermediate products arising at various stages of the process were known it might become possible to supply these instead of sugar and its precursors to the body and thus circumvent the inability to start the oxidation of the carbohydrate food. Various intermediate possibilities have been postulated by biochemists; among them, lactic acid, glyceric aldehyde, methyl glyoxal, pyruvic acid, and dihydroxyacetone. The latter substance, $C_3H_6O_3$, has appeared to be particularly promising as an intermediate "substitute" for the body's sugar. The studies of Markowitz and Campbell[1] at the University of Toronto afford a new interpretation of the ready disappearance of dihydroxyacetone in the organism. It is converted into glucose by the liver and used as such. Consequently, as it does not arise in the normal path of the catabolism of glucose, it cannot be used by the diabetic patient more effectively than sugar itself.[2] The hope of being able to furnish the new substance in place of sugar to patients with diabetes so as to produce energy and act as an antiketogenic substance has thus been shattered.

PROCEEDINGS OF THE WASHINGTON SESSION

MINUTES OF THE SEVENTY-EIGHTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT WASHINGTON, D. C., MAY 16-20, 1927

(Concluded from page 1816)

MINUTES OF THE SECTIONS

SECTION ON PRACTICE OF MEDICINE

Wednesday, May 18—Morning

The meeting was called to order at 9:30 by the chairman, Dr. Rollin T. Woodyatt, Chicago.

Drs. W. Warner Watkins, Phoenix, Ariz., and G. C. Lake, Washington, D. C., presented a paper on "Malta Fever: Epidemic of Thirty-Five Cases." Discussed by Drs. Allen C. Eustis, New Orleans; F. C. A. Mattison, Pasadena, Calif., and G. C. Lake, Washington, D. C.

Dr. Joseph E. Moore, Baltimore, read a paper on "Treatment of Syphilis of the Central Nervous System." Discussed by Drs. L. M. Gaines, Atlanta, Ga.; Homer F. Swift, New York; P. A. O'Leary, Rochester, Minn.; Gerald B. Webb, Colorado Springs, Colo., and Joseph E. Moore, Baltimore.

Drs. William C. Voorsanger and Fred Firestone, San Francisco, presented a paper on "Undiagnosed Cough: An Intensive Study of Two Hundred Cases."

Drs. Chevalier Jackson, Thomas McCrae and Elmer H. Funk, Philadelphia, presented a paper on "New Growth of the Lungs."

These two papers were discussed by Drs. Gerald B. Webb, Colorado Springs, Colo.; Hugh J. Morgan, Nashville, Tenn.; Paul H. Ringer, Asheville, N. C.; Elmer H. Funk, Philadelphia; John A. Lichty, Clifton Springs, N. Y.; H. F. Stoll, Hartford, Conn.; A. H. Rowe, Oakland, Calif.; C. L. Minor, Asheville, N. C.; William C. Voorsanger, San Francisco; Thomas McCrae, Philadelphia, and Chevalier Jackson, Philadelphia.

Dr. Douglas VanderHoof, Richmond, Va., read a paper on "The Medical Cure of Duodenal Ulcer." Discussed by Drs. Franklin W. White, Boston; John J. Gilbride, Philadelphia; George B. Eusterman, Rochester, Minn.; J. N. Hall, Denver; Seale Harris, Birmingham, Ala., and Douglas VanderHoof, Richmond, Va.

A motion was made by Dr. Henry A. Christian, Boston, to appoint a small committee to cooperate with the Council on Pharmacy and Chemistry in the study of heroin. The motion was seconded and carried.

Dr. Christian also spoke on a fund for the Section on Practice of Medicine, and a collection was taken up.

Dr. J. B. McElroy, Memphis, Tenn., read a paper on "Nephroses." Discussed by Drs. Alfred Stengel, Philadelphia; Louis M. Warfield, Milwaukee; Rollin T. Woodyatt, Chicago; Thomas B. Futcher, Baltimore; H. A. Christian, Boston, and J. B. McElroy, Memphis, Tenn.

Dr. Louis M. Warfield, Milwaukee, read a paper on "Acute Pancreatitis Followed by Acute Diabetes."

Dr. I. I. Lemann, New Orleans, read a paper on "Diabetic Gangrene in the South."

These two papers were discussed by Drs. Frederick M. Allen, New York; Elliott P. Joslin, Boston; James E. Paullin, Atlanta, Ga.; Allen C. Eustis, New Orleans; Abraham J. Rubenstone, Philadelphia, and Louis M. Warfield, Milwaukee.

Thursday, May 19—Morning

Dr. Rollin T. Woodyatt, Chicago, read the chairman's address, entitled "Psychic and Emotional Factors in General Diagnosis and Treatment."

Dr. J. Ramsay Hunt, New York, read a paper on "General Principles Pertaining to the Recognition and Management of Psychic and Emotional Influences."

Dr. Nellis B. Foster, New York, read a paper on "Emotional and Psychic Factors in the Course of Arterial Hypertension and Heart Disease."

Dr. James S. McLester, Birmingham, Ala., read a paper on "Emotional and Psychic Factors in the Production of Disorders of the Digestive Organs."

Dr. Charles Hugh Neilson, St. Louis, read a paper on "Emotional and Psychic Factors in the Course of Diabetes Mellitus and Exophthalmic Goiter, Laryngology and Ophthalmology."

These four papers were discussed by Drs. E. Bates Block, Atlanta, Ga.; Arthur D. Dunn, Omaha; William A. White, Washington, D. C.; Max Einhorn, New York; Eugene S. Kilgore, San Francisco; Edmund Jacobson, Chicago; Stewart R. Roberts, Atlanta, Ga.; E. C. Rosenow, Rochester, Minn.; J. Ramsay Hunt, New York, and Charles Hugh Neilson, St. Louis.

The chairman appointed a committee to reconsider the question and draft resolutions concerning the reintroduction of heroin into the pharmacopeia, consisting of: Drs. Alexander Lambert, New York, chairman; W. S. Thayer, Baltimore; Eugene S. Kilgore, San Francisco, and Stewart R. Roberts, Atlanta, Ga.

Dr. Henry A. Christian, Boston, spoke on the fund.

Dr. David I. Macht, Baltimore, read a paper on "Experimental Contribution on Etiology, Diagnosis and Treatment of Pernicious Anemia."

Drs. George R. Minot and William P. Murphy, Boston, presented a paper on "Treatment of Pernicious Anemia by a Diet Rich in Liver."

These two papers were discussed by Drs. H. M. Conner, Rochester, Minn.; Walter L. Bierring, Des Moines, Iowa; James H. Means, Boston; John A. Lichty, Clifton Springs, N. Y.; David I. Macht, Baltimore, and George R. Minot, Boston.

Friday, May 20—Morning

The following officers were elected: chairman, Dr. James E. Paullin, Atlanta, Ga.; vice chairman, Dr. William H. Robey, Boston; secretary, Dr. Bryce W. Fontaine, Memphis, Tenn.; delegate, Dr. Henry A. Christian, Boston; alternate, Dr. Joseph L. Miller, Chicago; trustees for the fund, Dr. W. T. Longcope, Baltimore, and Dr. W. L. Bierring, Des Moines, Iowa.

Dr. O. H. Perry Pepper, Philadelphia, read a paper on "The Hematology of Subacute Endocarditis."

Dr. Stewart R. Roberts, Atlanta, Ga., read a paper on "Obesity and Heart Disease."

Drs. John Phillips and John P. Anderson, Cleveland, presented a paper on "Cardiac Disturbances Associated with Diseases of the Thyroid Gland."

Dr. C. T. Stone, Galveston, Texas, read a paper on "Heart Disease as Seen in a Southern Clinic: A Clinical and Pathologic Survey."

These four papers were discussed by Drs. Glenville Giddings, Atlanta, Ga.; James E. Paullin, Atlanta, Ga.; Albert A. Hornor, Boston; W. S. Thayer, Baltimore; Paul D. White, Boston (read by Dr. Howard B. Sprague, Boston); John J. Sampson, San Francisco; Nathan Rosenthal, New York; Lulu Hunt Peters, New York; J. Marion Read, San Francisco; Eugene S. Kilgore, San Francisco, and Cary Eggleston, New York.

Dr. H. S. Plummer, Rochester, Minn., read a paper on "Factors in the Postoperative Mortality of Exophthalmic Goiter." Discussed by Drs. Frank H. Lahey, Boston, and W. S. Thayer, Baltimore.

Dr. Warfield T. Longcope, Baltimore, read a paper on "Observations on Metabolic Disturbances in Scleroderma."

Discussed by Drs. John A. Stokes, Philadelphia; Benjamin Jablons, New York; Henry A. Christian, Boston, and Warfield T. Longcope, Baltimore.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

Wednesday, May 18—Afternoon

The meeting was called to order at 2 o'clock by the chairman, Dr. J. Tate Mason, Seattle.

The following papers were read as a symposium on "Fractures":

Dr. Robert B. Osgood, Boston: "Diagnosis and Treatment of Compression Fractures of the Spine." Discussed by Drs. Alan DeForest Smith, New York; James O. Wallace, Pittsburgh, and Robert B. Osgood, Boston.

Dr. Nathaniel Allison, Boston: "Diagnosis and Treatment of Fractures of the Lower Extremity of the Humerus." Discussed by Drs. J. M. Hitzrot, New York, and Fraser B. Gurd, Montreal.

Dr. William Darrach, New York: "Diagnosis and Treatment of Fractures of the Lower Extremity of the Radius." Discussed by Dr. R. S. Hooker, New York.

Dr. Philip Wilson, Boston: "Diagnosis of Fractures of the Os Calcis." Discussed by Drs. F. J. Cotton, Boston; P. B. Magnuson, Chicago, and Philip Wilson, Boston.

Thursday, May 19—Afternoon

The meeting was called to order at 2 o'clock by the chairman.

Dr. J. Tate Mason, Seattle, read the chairman's address, entitled "The Trends of Surgery."

Dr. Charles Bagley, Jr., Baltimore, read a paper on "Meningeal Irritation Resulting from the Extravasation of Blood in the Subarachnoid Space." Discussed by Drs. Harry H. Kerr, Washington, D. C., and Francis C. Grant, Philadelphia.

Dr. Carl H. Hedblom, Chicago, read a paper on "The Early Diagnosis and Surgical Treatment of Bronchiectasis." Discussed by Drs. Howard Lilienthal, New York, and Carl A. Hedblom, Chicago.

Dr. Fred W. Rankin, Rochester, Minn., read a paper on "Colostomy and Posterior Resection for Carcinoma of the Rectum." Discussed by Dr. Daniel F. Jones, Boston; Damon B. Pfeiffer, Philadelphia; Charles T. Souther, Cincinnati, and Fred W. Rankin, Rochester, Minn.

Dr. Richard Lewisohn, New York, read a paper on "Partial Gastrectomy Versus Gastro-Enterostomy in the Surgical Treatment of Gastric and Duodenal Ulcers."

Dr. J. Shelton Horsley, Richmond, Va., read a paper on "Partial Gastrectomy."

Dr. Donald C. Balfour, Rochester, Minn., read a paper on "The Treatment of Lesions of the Stomach and Duodenum Associated with Hemorrhage."

These three papers were discussed by Drs. Charles H. Mayo, Rochester, Minn.; George W. Crile, Cleveland; Frank H. Lahey, Boston; John J. Gilbride, Philadelphia; E. R. Arn, Dayton, Ohio; Richard Lewisohn, New York; J. Shelton Horsley, Richmond, Va., and Donald C. Balfour, Rochester, Minn.

Dr. John Homer Woolsey, San Francisco, read a paper on "Diaphragmatic Hernia." Discussed by Drs. Philemon E. Truesdale, Fall River, Mass.; J. Earl Else, Portland, Ore., and Carl A. Hedblom, Chicago.

Friday, May 20—Afternoon

The meeting was called to order at 2 o'clock by the chairman.

The following officers were elected: chairman, Dr. J. Shelton Horsley, Richmond, Va.; vice chairman, Dr. Harold Brunn, San Francisco; secretary, Dr. Frank H. Lahey, Boston; delegate, Dr. Evart Graham; alternate, Dr. J. Tate Mason.

Dr. E. R. Arn, Dayton, Ohio, read a paper on "The Surgical Treatment of Goiter with Hyperthyroidism."

Dr. J. Earl Else, Portland, Ore., read a paper on "Regeneration of the Thyroid Gland and the Prevention of Recurrent Goiters."

Dr. Martin B. Tinker, Ithaca, N. Y., read a paper on "Some Surgical Problems of Thyroiditis."

These three papers were discussed by Drs. Harry G. Sloan, Cleveland; Howard M. Clute, Boston; E. P. Sloan, Bloomington, Ill.; Wallace I. Terry, San Francisco; J. Tate Mason, Seattle; Lawrence W. Smith, Boston; E. R. Arn, Dayton, Ohio; J. Earl Else, Portland, Ore., and Martin B. Tinker, Ithaca, N. Y.

Dr. John O. Bower, Philadelphia, read a paper on "Controllable Factors in the Mortality of Acute Appendicitis, Fallacies in Present-Day Teaching." Discussed by Drs. Stanley P. Reimann, Philadelphia; Charles T. Souther, Cincinnati; J. H. Clark, Philadelphia, and John O. Bower, Philadelphia.

Dr. Donald Macrae, Jr., Council Bluffs, Iowa, read a paper on "Management of Acute Conditions of the Abdomen Complicated by Marked Ileus or Septic Invasion of the Peritoneum." Discussed by Drs. Edward P. Richardson, Boston; J. Shelton Horsley, Richmond, Va., and Donald Macrae, Jr., Council Bluffs, Iowa.

Dr. A. I. MacKinnon, Lincoln, Neb., read a paper on "Jejunostomy: Technic and Indication for this Life-Saving Operation." Discussed by Drs. Charles Gordon Heyd, New York; John H. Woolsey, San Francisco; Donald Macrae, Jr., Council Bluffs, and A. I. MacKinnon, Lincoln, Neb.

Dr. George P. Muller, Philadelphia, read a paper on "The Noncalculous Gallbladder." Discussed by Drs. Lester R. Whitaker, Boston; J. Earl Else, Portland, Ore., and George P. Muller, Philadelphia.

Dr. Amos R. Koontz, Baltimore, read a paper on "Clinical Results in the Use of Dead (Preserved) Fascia Graft for Hernia Repair." Discussed by Drs. Harvey B. Stone, Baltimore; Henry W. Cave, New York; B. L. Coley, New York, and Amos R. Koontz, Baltimore.

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

Wednesday, May 18—Morning

The meeting was called to order at 9:05 by the chairman, Dr. Arthur H. Curtis, Chicago.

Dr. F. C. Holden, New York, read a paper on "Certain Relations Between Governments in Northern Europe and the Teaching and Practice of Gynecology and Obstetrics."

Dr. Franklin H. Martin, Chicago, read a paper on "Gynecology and Obstetrics in Relation to Hospital Betterment."

Dr. George W. Kosmak, New York, read a paper on "Results of Supervised Midwife Practice in Certain European Countries: Can We Draw a Lesson from This for the United States?"

Dr. Stuart B. Blakely, Binghamton, read a paper on "Teaching Prenatal Care by Means of Posters."

Dr. Effa V. Davis, Chicago, read a paper on "The Effect of Prenatal Care on the Size and Health of the New-Born."

Dr. S. Josephine Baker, Stamford, Conn., read a paper on "Maternal Mortality in the United States."

Dr. L. Maud Parker, Seattle, read a paper on "Postnatal Maternal Care."

Drs. Harold Bailey and H. C. Williamson, New York, presented a paper on "Trial Labor as a Procedure in the Treatment of Patients with Contracted Pelves."

Dr. Alice F. Maxwell, San Francisco, read a paper on "Dystocia in Contracted Pelves."

These nine papers were discussed by Drs. J. W. Williams, Baltimore; Frank Lynch, San Francisco; Rudolph W. Holmes, Chicago; R. L. Dickinson, New York; John O. Polak, Brooklyn; J. B. De Lee, Chicago; Dr. Effa V. Davis, Chicago, and H. C. Williamson, New York.

Dr. George W. Kosmak, New York, presented the following resolution to be acted on at the Friday morning session:

> *Resolved*, That the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association participate in the activities of the Joint Committee on Maternal Welfare by the annual appointment by the chairman of the section of three Fellows as members of this committee.

Thursday, May 19—Morning

Dr. Arthur H. Curtis, Chicago, read the chairman's address, entitled "Indications for Surgical Intervention in Pelvic Lesions of Infectious Origin, Based on Seventeen Years' Laboratory and Clinical Study."

Dr. Norman F. Miller, Iowa City, read a paper on "Posture Studies in Gynecology." Discussed by Drs John O Polak, Brooklyn; Emil Novak, Baltimore, and Norman F. Miller, Iowa City.

Drs Howard A. Kelly and Curtis F Burnam, Baltimore, presented a paper on "High Frequency Currents in Gynecology." Discussed by Drs George Wyeth, New York; Grant Ward, Baltimore, and Howard A Kelly, Baltimore.

Dr. Samuel R. Meaker, Boston, read a paper on "A Working Classification of the Causes of Sterility"

Dr I C Rubin, New York, read a paper on "Clinical Study of Tubal Patency in Six Hundred Cases of Sterility by Method of Peruterine Insufflation Combined with Kymograph"

Drs. Robert T. Frank and M A Goldberger, New York, presented a paper on "Clinical Data Obtained with 'The F S H.' (Female Sex Hormone) Blood Test'

These three papers were discussed by Drs Donald N Macomber, Boston George G Ward, New York M A Goldberger, New York; Emil Novak, Baltimore Samuel B Meaker, Boston, I C Rubin, New York, and Robert T. Frank, New York

Dr Lucius E Burch Nashville, Tenn, read a paper on "Treatment of Pelvic Inflammation"

Drs John O Polak and Donald Tollerson, Brooklyn presented a paper on "The Sedimentation Test as Clinical Index in Postoperative Prognosis and Complications"

These two papers were discussed by Drs George G Ward New York Joseph L Baer, Chicago, William T Black Memphis, Tenn, R L Dickinson, New York Robert Young Sullivan, Washington, D C Channing W Barrett, Chicago Lucius E Burch, Nashville, Tenn, and John O Polak Brooklyn

Friday, May 20—Morning

The following officers were elected chairman, Dr. J C Litzenberg Minneapolis, vice chairman, Dr Edward Speidel, Louisville Ky secretary, Dr Carl Henry Davis Milwaukee delegate, Dr John O Polak, New York; alternate, Dr Lucius E Burch, Nashville, Tenn

The resolution presented by Dr George W Kosmak, New York, was adopted, and the following were appointed members of the Joint Committee on Maternal Welfare Dr Fred L Adair Minneapolis, Dr Rudolph W Holmes, Chicago, and Dr Robert D Mussey, Rochester, Minn

Drs Floyd E Keene H K Pancoast and E P Pendergrass Philadelphia, presented a paper on "Results of Irradiation in the Treatment of Ovarian Carcinoma' No discussion.

Dr Charles H Mayo, Rochester, Minn, read a paper on "A Case of Paroxysmal Hypertension with Retroperitoneal Nerve Tumor" Dr L G Rowntree, Rochester, Minn, who was to have discussed Dr. Mayo's paper was not present because of illness, but sent his discussion, which was read. Dr Mayo closed

Dr Louis Antupit Hartford, Conn, read a paper on "Postoperative Parotitis in Abdominal Surgery"

Dr. Robert L Craig, New York, read a paper on "Postoperative Ventral Hernia An Analysis of Seventy-Nine Cases Following Seven Thousand Six Hundred and Seventy-Two Laparotomies."

Dr William Thalhimer, Milwaukee, read a paper on "Laboratory Aid in Postoperative Care of Patients with Abdominal Operation."

Dr Waltman Walters, Rochester, Minn, read a paper on 'Causes and Treatment of the Toxemia of Clinical and Experimental Duodenal Fistula"

Dr. F. H. Lahey, Boston, read a paper on "The Management of Some Complications Following Abdominal Operations"

Drs George W. Crile and Charles C Higgins, Cleveland, presented a paper on "Prevention of Postoperative Complications"

These six papers were discussed by Drs. C. S. McVicar, Rochester, Minn.; J. Earl Else, Portland, Ore.; H. D. Furniss, New York; Channing W. Barrett, Chicago; Frank W. Lynch, San Francisco; P. B. Salatich, New Orleans; B. L. Coley, New York; Daniel H. Bessesen, Minneapolis; J L Baer, Chicago, Louis Antupit, Hartford, Conn.; Robert L Craig, New York; William Thalhimer, Milwaukee; Waltman Walters, Rochester, Minn, and George W. Crile, Cleveland.

SECTION ON OPHTHALMOLOGY

Wednesday, May 18—Afternoon

The meeting was called to order at 2 o'clock by the chairman Dr John A Donovan, Butte, Mont.

Dr John A Donovan, Butte, Mont, read the chairman's address

On motion of Dr Arnold Knapp, New York, seconded and carried, the regular order of business was suspended while Dr Hideyo Noguchi addressed the section on the progress of the work on trachoma among the Indians. Discussed by Dr Martin Cohen of New York. A vote of thanks was extended to Dr Noguchi for his kindness in addressing the section

Dr Martin Cohen, New York, read a paper on "Orbital Meningo-Encephalocele Associated with Microphthalmia: Report of Case' Discussed by Drs. Eugene M. Blake, New Haven Conn Lewis W. Crigler, New York; F. P. Calhoun, Atlanta Ga, and Martin Cohen, New York.

Dr Harry A Goalwin, New York, read a paper on "One Thousand Optic Canals A Clinical, Anatomic and Roentgenologic Study" Discussed by Drs. G. E. Pfahler, Philadelphia and H H. Tyson, New York.

Dr F. Park Lewis, Buffalo, read a paper on "A Nonoperative Treatment of Inflammatory Glaucoma"

Dr Harry S Gradle, Chicago, read a paper on "Conjunctival Drain of the Anterior Chamber: An Operative Technic Used in Absolute Glaucoma."

These two papers were discussed by Drs. Allen Greenwood, Boston, John Hunter, Toronto; John M. Wheeler, New York, J W. Charles, St Louis; H L. Hilgartner, Austin, Texas, Kaspar Pischel, San Francisco; William H. Crisp, Denver; F. Park Lewis, Buffalo, and Harry S. Gradle, Chicago

Dr Robert Von Der Heydt, Chicago, read a paper on "Stereophotography of the Anterior Eyeball and Fundus." Discussed by Drs Arthur J Bedell, Albany, N. Y.; Laura A. Lane, Baltimore; Harry S. Gradle, Chicago, and Robert Von Der Heydt, Chicago

Dr Alan C. Woods, Baltimore, read a paper on "Lens Protein and Its Fractions Preparation and Immunologic and Chemical Properties" Discussed by Drs. Zenas H. Ellis, New York, S. R Gifford, Omaha; A. E. Davis, New York; Isaac S Tassman, Philadelphia, and Alan C. Woods, Baltimore.

Thursday, May 19—Afternoon

Dr Kaspar Pischel, San Francisco, demonstrated the localization of foreign bodies in the eyeball by markers in the conjunctiva

Dr F O Schwartz, St Louis, presented a new instrument for use in the intracapsular and extracapsular method of cataract extraction.

Dr. G C Savage, Nashville, Tenn, presented a special spud and light.

Dr Daniel M Velez, Mexico, was introduced to the section

Dr Henning Ronne, Copenhagen, Denmark, read a paper on "The Different Types of the Pathologic Visual Field." No discussion

Dr. Walter I. Lillie, Rochester, Minn, read a paper on "Ocular Phenomena Produced by Basal Lesions of the Frontal Lobe." Discussed by Drs Henning Ronne, Copenhagen, Emory Hill, Richmond, Va.; George E. de Schweinitz, Philadelphia, and Walter I. Lillie, Rochester, Minn

Dr. Albert L Brown, Cincinnati, read a paper on "The Ocular Fundus in the Acute Toxemias. An Analysis of Eight

Hundred and Fifty Cases" Discussed by Dr James P. Fitzgerald, Chicago

Dr S. J. Beach, Portland, Maine, read a paper on "The Selection of Test Type for Refraction "

Dr David W. Wells, Boston, read a paper on "Cycloplegics in Refraction."

These two papers were discussed by Drs W B Lancaster, Boston, William Zentmayer, Philadelphia, Allen Greenwood, Boston, Linn Emerson, Orange, N J Edward Jackson, Denver, S W Newmayer, Philadelphia, Dorland Smith Bridgeport, Conn , William H Crisp, Denver, S J Beach, Portland, Maine and David W Wells, Boston

Dr Meyer Wiener, St Louis, read a paper on Epinephrine in Progressive Myopia" Discussed by Drs William H Crisp Denver, and Meyer Wiener, St Louis

Dr Harlow Brooks, New York, read a paper on 'The Ophthalmologic Needs of the Internist" Discussed by Drs E V L Brown, Chicago, William L Benedict Rochester, Minn , Thomas H Curtin New York and George S Derby, Boston

Dr Arnold Knapp, New York, chairman of the Executive Committee presented the following report

It seemed desirable to introduce at this time a part of our executive session on account of unexpected circumstances It refers to the bestowal of the Howe medal This medal as you know, was endowed by Dr Howe for the one who has most meritoriously contributed to ophthalmology

The Executive Committee takes great pleasure in recommending to this honor George E de Schweinitz (Applause)

Friday, May 20—Afternoon

Dr Harry S Gradle, Chicago, presented the report of the Committee on Compensation Tables, which was accepted and the committee continued.

Dr Edward Jackson, Denver, presented the report of the Committee on Authorized Methods of Determining the Power of Spectacle Lenses, which was accepted and the committee continued

Dr. Edward Jackson, Denver, also presented the report of the Committee on Optometry, which was adopted

The report of the Committee on Trachoma Among the Indians was presented by the chairman, Dr W H Wilder, Chicago, the report was accepted, and the committee was thanked for its work

Dr. Albert E Bulson, Jr, Fort Wayne, Ind, presented the report of the Committee on the Knapp Testimonial Fund, which was adopted

For the Committee on Awarding the Knapp Medal, Dr George S Derby reported that the committee recommended that no award be made this year

The report of the Committee on the American Board of Ophthalmic Examinations was read by Dr. Walter B Lancaster, Boston, the chairman, the report was received and the committee thanked for its work

Dr Harry S Gradle, Chicago, presented the report of the Committee on National Museum of Ophthalmic Pathology, which was received

Dr Albert E Bulson, Jr, Fort Wayne, Ind, reported for the Committee to Draw Up Resolutions Regarding Inadequate Lantern Device No action was necessary on the report

Dr Harry S Gradle, Chicago, in the absence of Dr Cassius Wescott, chairman of the Committee on Ways and Means of Continuing the Year Book, reported for that committee The report was adopted and the committee continued

Dr W H Wilder, Chicago, delegate of the section to the House of Delegates, reported the activities of the House at its Washington Session

It was voted, on motion of Dr Arnold Knapp, New York, that Prof Henning Ronne, Copenhagen Denmark, whose name was omitted by oversight from the list of names presented for election to Honorary Fellowship in the Association be presented at the next annual session for Honorary Fellowship

The following officers were elected chairman, Dr W B Lancaster, Boston, vice chairman, Dr Edmond E Blaauw, Buffalo; secretary, Dr. W C Finnoff, Denver; delegate, Dr W H Wilder, Chicago, alternate, Dr Harry S Gradle, Chicago member, Board of Ophthalmic Examinations, Dr W H Crisp Denver.

Drs Frederick H Verhoeff, Boston; Emory Hill, Richmond Va, and E V L Brown, Chicago, were elected members of the Committee on the Knapp Medal

Mr Lewis H Carris, managing director of the National Committee for the Prevention of Blindness, addressed the section and in accordance with his recommendation it was voted on motion of Dr George Derby that a committee be appointed from the section to cooperate with the National Committee for the Prevention of Blindness The chairman appointed the following committee Dr George Derby, Boston Dr William C Finnoff, Denver, Dr W H Luedde, St Louis

Dr G C Savage Nashville Tenn, read a paper on "The Treatment of the Intrinsic and Extrinsic Ocular Muscles" Discussed by Drs Edward Jackson, Denver, Hiram Woods, Baltimore, L W Fox Philadelphia, Oscar Wilkinson, Washington, D C, David W Wells, Boston, and G C Savage Nashville Tenn

Dr John O McReynolds, Dallas, Texas, read a paper on "The Crystalline Lens System"

Dr Walter R Parker Detroit read a paper on 'Cataract Extraction Comparative Results Obtained by the Combined, Simple and Knapp-Torok Methods of Procedure"

Dr E B Dunphy, Boston, read a paper on Loss of Vitreous in Cataract Extraction"

Dr C S O'Brien Iowa City, read a paper on Local Anesthesia in Ophthalmic Surgery"

Dr L Webster Fox, Philadelphia, read a paper on "Congenital Cataract A Plea for Variety in Its Surgical Treatment"

These five papers were discussed by Drs W H Luedde, St Louis, E C Ellett, Memphis, Tenn , Arnold Knapp, New York, Albert E Bulson Jr, Fort Wayne, Ind , E E Holt, Jr, Portland, Maine, Daniel M Velez, Mexico, F Park Lewis, Buffalo, Edmond E Blaauw, Buffalo, W B Lancaster, Boston, H W Woodruff, Joliet, Ill , Oscar Wilkinson, Washington, D C , W H Wilder, Chicago, Louie V Stegman, Battle Creek, Mich , George Huston Bell, New York, R H T Mann, Texarkana, Texas, and Walter R Parker, Detroit

Drs Hugo A Kiefer and Leon Shulman, Los Angeles, presented a paper on "Personal Observation on Tuberculosis of the Eye The Use of Tuberculin in Its Diagnosis and Treatment" Discussed by Drs T B Holloway, Philadelphia, Malcolm C Rose, New York, George S Derby, Boston, and Leon Shulman, Los Angeles

SECTION ON LARYNGOLOGY, OTOLOGY, AND RHINOLOGY

Wednesday, May 18—Morning

The meeting was called to order at 9 o'clock by the chairman, Dr George M Coates, Philadelphia

Dr George M Coates, Philadelphia, read the chairman's address, entitled "Training in Otolaryngology"

Dr Georges Portmann, Bordeaux, France, read a paper on 'Researches on the Saccus Endolymphaticus Results and Surgical Applications" Discussed by Drs Wells P Eagleton, Newark, N J , George E Shambaugh, Chicago, Lester Mead Hubby, New York, James A Flynn, Washington, D C , S A Schuster, El Paso, Texas, and Georges Portmann, Bordeaux, France

Dr Lester Mead Hubby, New York, read a paper on "The Modus Operandi of Vertigo" Discussed by Drs John Hunter, Toronto, I Leon Meyers, Los Angeles, and Lester Mead Hubby, New York

Dr E R Carpenter, Dallas, Texas, read a paper on "The Importance of Ophthalmology and Otology in the Early Diagnosis of Brain Tumors" Discussed by Drs Lewis Fisher, Philadelphia, Conrad Berens, Jr, New York, and E R Carpenter, Dallas, Texas

Dr. Lee M. Hurd, New York, read a paper on "The Use of Larding Pork to Control Hemorrhage." Discussed by Drs. Walter A. Wells, Washington, D C; George M. Coates, Philadelphia, and Lee M Hurd, New York.

Dr. George B. Jobson, Jr., Franklin, Pa, read a paper on "The Surgical Correction of Cleft Lip and Cleft Palate" Discussed by Drs. George M. Dorrance, Philadelphia; Thomas E. Carmody, Denver, and George B. Jobson, Jr, Franklin, Pa.

THURSDAY, MAY 19—MORNING

Dr. Bert Hempstead, Rochester, Minn, read a paper on "The Intranasal Surgical Treatment of Chronic Maxillary Sinusitis" Discussed by Drs Horace Newhart, Minneapolis, William Mithoefer, Cincinnati, Sidney Israel, Houston, Texas, J A Pratt, Minneapolis; James J King, New York, R G Reaves, Knoxville, Tenn, and Bert Hempstead, Rochester, Minn

Dr William Mithoefer, Cincinnati, read a paper on "A Critical Review of the External Frontal Sinus Operation" Discussed by Drs Joseph D Heitger, Louisville, Ky; Sam Earl Roberts, Kansas City, Mo; J. A Pratt, Minneapolis, Lee M Hurd, New York, S A Schuster, El Paso, Texas, Austin A Hayden, Chicago, Oscar Wilkinson, Washington, D C, M M Cullom, Nashville, Tenn, William Mithoefer, Cincinnati

Dr F E Hasty, Nashville, Tenn, read a paper on "Paranasal Sinus Infection and Swimming." Discussed by Drs. H Marshall Taylor, Jacksonville, Fla; Joseph D Heitger, Louisville, Ky.; George F Fiske, Chicago; M. M Cullom, Nashville, Tenn, H A Rothrock, Westchester, Pa, and F E. Hasty, Nashville, Tenn

Dr. George E. Shambaugh, Chicago, read a paper on "The Problem of Graduate Training in Clinical Medicine" Discussed by Drs. Harris P Mosher, Boston, L. W. Dean, Iowa City, Austin A Hayden, Chicago; Reese Patterson, Knoxville, Tenn; Horace Newhart, Minneapolis, and George E. Shambaugh, Chicago

Dr G Allen Robinson, New York, read a paper on "Progress and Results of Radium Treatment in Neoplasms of the Upper Air Passages" Discussed by Drs Thomas E Jones, Cleveland; Homer Dupuy, New Orleans, and G. Allen Robinson, New York

Dr M C Myerson, Brooklyn, read a paper on "A Manifestation of Uremia in the Pharynx, Larynx, Trachea and Bronchi" Discussed by Dr. N M. Keith, Rochester, Minn.

Dr George D Wolf, New York, read a paper on "Dysphonia Its Significance and Management" Discussed by Drs Frank R Spencer, Boulder, Colo, and Homer Dupuy, New Orleans

Dr Samuel Iglauer, Cincinnati, presented a patient, who demonstrated the use of an artificial larynx

FRIDAY, MAY 20—MORNING

The report of the Executive Committee was presented by Dr Samuel Iglauer, Cincinnati A motion was made, seconded, and carried to adopt the report

The following officers were elected chairman, Dr Frank R Spencer, Boulder, Colo; vice chairman, Dr. Hermon Marshall Taylor, Jacksonville, Fla; Secretary, Dr. William Valentine Mullin, Cleveland, delegate, Dr. Burt R Shurly, Detroit, alternate, Dr William P Wherry, Omaha; executive committee, Dr Samuel Iglauer, Cincinnati, and Dr. Frank R Spencer, Boulder, Colo

Dr M Joseph Mandelbaum, New York, presented a reverse tracheotome

Dr L E Daugherty, Cumberland, Md, presented a new antrum needle

Dr W P Reaves, Greensboro, N. C, presented a sternoradiographic angle head table

Dr F. P. Herman, West Palm Beach, Fla, presented a tonsillectome using diathermic principles

The report of the Committee on Necrology was read by Dr. William V Mullin, Cleveland It was moved, seconded and carried that the report be adopted.

The report of the Committee on Lye Legislation was presented by Dr H. B. Orton, Newark, N. J. A motion was made, seconded and carried that the report be adopted and the committee continued

The report of the Committee on Otorhinologic Hygiene of Swimming was presented by Dr. Marshall Taylor, Jacksonville, Fla A motion was made, seconded and carried that the report be adopted and the committee continued.

The report of the Committee on the Adult Deaf and the Deafened Child was presented by Dr. Harold M. Hays, New York. A motion was made, seconded and carried that the report be adopted and the committee continued.

The following papers were read as a symposium on "Bronchial Asthma":

Dr James S McLaughlin, Philadelphia: "Skin Reactions in Patients with Asthma."

Dr J Alexander Clarke, Jr., Philadelphia: "The Study and Treatment of Asthma."

Dr Philip S Stout, Philadelphia: "Nose and Throat Observations in the Examination of Patients with Bronchial Asthma"

Dr W. F. Manges, Philadelphia: "Roentgen-Ray Observations in Asthma"

Dr Louis H Clerf, Philadelphia: "Bronchoscopy as an Aid in the Diagnosis and Treatment of Bronchial Asthma."

Dr John Eiman, Philadelphia: "Studies in the Etiology of Bronchial Asthma"

Dr H B Wilmer, Philadelphia: "Studies in the Treatment of Bronchial Asthma."

Dr Edwin McGinnis, Chicago: "Asthma: From the Standpoint of the Rhinologist."

These eight papers were discussed by Drs. George Piness, Los Angeles, Grafton Tyler Brown, Washington, D. C.; James T. Wolfe, Washington, D. C.; George N. Jack, Buffalo; Austin A Hayden, Chicago; H. M. Davison, Atlanta, Ga.; Albert H Rowe, Oakland, Calif.; Howard L. Stitt, Cincinnati, Frank R. Spencer, Boulder, Colo.; M. C. Myerson, Brooklyn; J A Pratt, Minneapolis; Leon Unger, Chicago; James S. McLaughlin, Philadelphia; Philip S. Stout, Philadelphia; Louis H Clerf, Philadelphia; H. B. Wilmer, Philadelphia, and Edwin McGinnis, Chicago.

SECTION ON DISEASES OF CHILDREN

WEDNESDAY, MAY 18—AFTERNOON

The *meeting* was called to order at 2:15 by the chairman, Dr H J. Gerstenberger, Cleveland.

Dr. H J Gerstenberger, Cleveland, read the chairman's address

The address of Dr. Gregorio Araoz Alfaro, Buenos Aires, Argentina, was read by title.

Dr. W. D Stroud, Philadelphia, read a paper on "Results in the Convalescent Care of Two Hundred and Twenty-Five Children with Heart Disease Over a Period of Five Years."

Dr. William St. Lawrence, New York, read a paper on "Question of Exercise for Children with Organic Disease of the Heart"

Dr A. D Kaiser, Rochester, N. Y, read a paper on "Relation of Tonsils to Rheumatic Fever, Chorea, and Heart Disease in Children"

These three papers were discussed by Drs. H. F. Swift, New York, Hugh McCulloch, St. Louis; J. L. Morse, Boston; Harold E B. Pardee, New York; Howard B. Sprague, Boston; Frank C Neff, Kansas City, Mo.; Myer Solis-Cohen, Philadelphia; Franklin P. Gengenbach, Denver; George D. Scott, New York; Stanley Nichols, Long Branch, N J, and William St Lawrence, New York.

The chairman appointed an auditing committee on the Jacobi Fund, consisting of: Drs. Samuel S. Adams, Washington, D. C, and H Leslie Moore, Dallas, Texas.

Dr. Joseph Brennemann, Chicago, read a paper on "Congenital Anorectal Stricture with Megacolon." Discussed by Drs J. P. Crozer Griffith, Philadelphia and W. A. Mulherin, Augusta, Ga

Dr. Henry F. Helmholz, Rochester, Minn, read a paper on "Congenital Anomalies of the Urinary Tract." Discussed by Drs. Isaac A. Abt, Chicago, and Hermon C. Bumpus, Rochester, Minn

Dr. W. Walter Wasson, Denver, read a paper on "Thymic Stridor." Discussed by Drs. H F. Helmholz, Rochester, Minn.; H. L. Moore, Dallas, Texas; Isaac A. Abt, Chicago; J. L. Morse, Boston; T. E. Carmody, Denver; Ludo von Meysenbug, New Orleans; J. Victor Greenebaum, Cincinnati, and W. Walter Wasson, Denver.

Thursday, May 19—Afternoon

The meeting was called to order at 2:15 by the chairman.

Dr. Borden Smith Veeder was appointed chairman of a committee to work with the Teachers Association.

The report of the Committee on Education of Pediatrics was read and accepted.

The following papers were read as a symposium on "Pulmonary and Bronchial Gland Tuberculosis":

Dr. E. L. Opie, Philadelphia: "Pulmonary and Bronchial Gland Tuberculosis."

Dr. T. C. Hempelmann, St. Louis: "Clinical Diagnosis of Pulmonary and Bronchial Gland Tuberculosis."

Dr. C. W. Burhans, Cleveland: "Tuberculin and Serodiagnosis of Pulmonary and Bronchial Gland Tuberculosis."

Dr. H. K. Dunham, Cincinnati: "Roentgenographic Diagnosis of Pulmonary and Bronchial Gland Tuberculosis."

Dr. J. C. Gittings, Philadelphia: "Pulmonary and Bronchial Gland Tuberculosis: Prognosis, Prophylaxis and Therapy."

These five papers were discussed by Drs. Charles H. Smith, New York; John A. Foote, Washington, D. C.; Harry M. Greenwald, Brooklyn; Julius H. Hess, Chicago; Eugene L. Opie, Philadelphia; T. C. Hempelmann, St. Louis; C. W. Burhans, Cleveland; H. K. Dunham, Cincinnati, and J. C. Gittings, Philadelphia.

Friday, May 20—Afternoon

The meeting was called to order at 2:15 by the vice chairman, Dr. Edgar P. Copeland, Washington, D. C.

The following officers were elected: chairman, Dr. Hugh McCulloch, St. Louis; vice chairman, Dr. Rood W. Taylor, Minneapolis; secretary, Dr. C. A. Aldrich, Winnetka, Ill; delegate, Dr. Isaac A. Abt, Chicago; alternate, Dr. L. T. Royster, University, Va.

Dr. Isaac A. Abt, Chicago, was nominated to succeed himself as member of the Jacobi Committee, and Dr. Frank C. Neff, Kansas City, Mo., to succeed himself.

A committee on Pediatric Teaching was appointed, consisting of Drs. T. C. Hempelmann, St. Louis, chairman; Paul W. Emerson, Boston; J. Victor Greenebaum, Cincinnati, and E. C. Mitchell, Memphis, Tenn.

A committee for the Study of State Board Requirements in Pediatrics was appointed, consisting of Drs. W. A. Mulherin, Augusta, Ga.; John Aikman, Rochester, N. Y.; H. L. Dwyer, Kansas City, Mo., and Joseph B. Bilderback, Portland, Ore.

The report of the Committee on Obituaries was presented and adopted.

The report of the Committee on the Jacobi Fund was presented and adopted.

A partial report of the Committee for Revision of Causes of Death in the New-Born was made by Dr. John A. Foote, Washington, D. C., and adopted.

The following resolutions were presented and adopted by rising vote:

Resolved, That the Section on Diseases of Children of the American Medical Association expresses its gratitude and thanks to that organization, and that the secretary be instructed to convey to them, by letter, the sentiment contained in this resolution.

In recognition of the delightful and unusual entertainment furnished by Mr. George O'Connor, of this city, at the section banquet, held at the Willard Hotel, May 18, 1927, be it

Resolved, That the Section on Diseases of Children of the American Medical Association transmit to Mr. O'Connor, through the secretary, the sincere thanks and appreciation of this organization.

As an expression of thanks and of our sincere gratitude for the many kind favors and the genuine hospitality shown to the members of this section by Drs. Edgar P. Copeland, John A. Foote and Frank Leech, all of Washington, D. C., be it

Resolved, That the Section on Diseases of Children of the American Medical Association expresses to these physicians, through the secretary, its profound thanks for their many kind acts and tactful entertainments.

Dr. C. Anderson Aldrich, Winnetka, Ill., read a paper on "The Prevention of Poor Appetite in Children."

Dr. L. W. Sauer, Evanston, Ill., read a paper on "The Malnourished Child: An Individual Intensive Method of Treatment."

These two papers were discussed by Drs. L. T. Royster, University, Va.; John A. Foote, Washington, D. C.; E. J. Huenekens, Minneapolis; Oliver W. Hill, Knoxville, Tenn.; Alfred J. Scott, Los Angeles; M. L. Turner, Des Moines, Iowa; C. G. Grulee, Chicago; Fred Moore, Des Moines, Iowa; C. Anderson Aldrich, Winnetka, Ill, and L. W. Sauer, Evanston, Ill.

Dr. J. T. Christison, St. Paul, read a paper on "Actinomycosis in the Lungs of Children." Discussed by Drs. J. C. Gittings, Philadelphia; H. F. Helmholz, Rochester, Minn.; Michael G. Wohl, Omaha, and J. T. Christison, St. Paul.

Dr. J. Buren Sidbury, Wilmington, N. C., read a paper on "Five Hundred Cases of Transfusion in Infancy." Discussed by Drs. C. G. Grulee, Chicago; Ludo von Meysenbug, New Orleans; W. C. Davison, Baltimore; Franklin P. Gengenbach, Denver; J. C. Gittings, Philadelphia; C. Ulysses Moore, Portland, Ore., and J. Buren Sidbury, Wilmington, N. C.

Drs. E. S. Platou and F. W. Schlutz, Minneapolis, presented a paper on "A Clinical Study of the Treatment of Erysipelas."

Dr. C. Ulysses Moore, Portland, Ore., read a paper on "Breast Feeding in Older Infants." Discussed by Dr. F. W. Schlutz, Minneapolis.

Dr. J. A. Henske, Omaha, read a paper on "Importance of Pediatric Care in Operative Treatment of Harelip and Cleft Palate." Discussed by Drs. F. W. Schlutz, Minneapolis, and John A. Foote, Washington, D. C.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

Wednesday, May 18—Afternoon

The meeting was called to order at 2 o'clock, by the chairman, Dr. W. de B. MacNider, Chapel Hill, N. C.

Dr. J. A. E. Eyster, Madison, Wis., read a paper on "Venous Pressure in Cardiac Decompensation."

Drs. Robert A. Hatcher, New York, and Soma Weiss, Boston, presented a paper on "The Seat of the Emetic Action of Digitalis Bodies."

Drs. Robert L. Levy and Thomas T. Mackie, New York, presented a paper on "Drug Treatment of Heart Disease."

Dr. Paul D. White, Boston, read a paper on "The Treatment of Heart Disease Other Than by Drugs."

Dr. J. Marion Read, San Francisco, read a paper on "Treatment of Cardiac Disturbance Due to Thyroid Disease."

Dr. L. A. Conner, New York, read a paper on "The Rehabilitation of Cardiac Patients Through Organized Effort."

These six papers were discussed by Drs. John Wyckoff, New York; Louis Faugeres Bishop, New York; Cary Eggleston, New York; H. S. Plummer, Rochester, Minn.; John P. Anderson, Cleveland; James Z. Naurison, Springfield, Mass.; Norman M. Keith, Rochester, Minn.; J. A. E. Eyster, Madison, Wis.; Thomas T. Mackie, New York; J. Marion Read, San Francisco, and L. A. Conner, New York.

Thursday, May 19—Afternoon

The chairman appointed a Nominating Committee consisting of Drs. Walter C. Alvarez, Rochester, Minn., chairman; Paul V. Ledbetter, Houston, Texas, and Howard B. Sprague, Boston.

Dr. W. de B. MacNider, Chapel Hill, N. C., read the chairman's address, entitled "Further Studies Concerning the Acid-Base Equilibrium of the Blood in Pregnant Animals." Discussed by Drs. William Thalhimer, Milwaukee, I. M. Procter, Raleigh, N. C., and W. de B. MacNider, Chapel Hill, N. C.

Dr. C. C. Bass, New Orleans, was unable to come to Washington to read his paper on "Fundamental Principles Underlying the Use of Specific Remedies for Infectious Diseases, with Especial Reference to Quinine in Malaria" on account of the situation resulting from the flood disaster in the Mississippi Valley.

Drs. A. M. Snell and J. F. Weir, Rochester, Minn., presented a paper on "Medical Treatment in Diseases of the Liver and Bile Passages." Discussed by Drs. Norman M. Keith, Rochester, Minn., and A. M. Snell, Rochester, Minn.

Dr. W. D. James, Hamlet, N. C., read a paper on "Relative Value of Deep Roentgen Ray, Radium, Myomectomy and Hysterectomy in Uterine Fibromyoma."

Dr. Charles C. Norris, Philadelphia, read a paper on "The Use of Radium in Gynecology."

These two papers were discussed by Drs. C. R. Crutchfield, Nashville, Tenn.; W. D. James, Hamlet, N. C., and Charles C. Norris, Philadelphia.

Dr. Guy Hinsdale, Hot Springs, Va., read a paper on "General Survey of the Actual Therapeutic Value of Hydrotherapy." Discussed by Drs. James M. Anders, Philadelphia; George Knapp Abbott, Takoma Park, Md.; Guy Hinsdale, Hot Springs, Va., and H. D. Offutt, Washington, D. C.

Dr. F. B. Granger, Boston, read a paper on "The Use and Abuse of Physical Therapeutics." Discussed by Drs. Richard Kovacs, New York, and Frank A. Davis, New York.

Friday, May 20—Afternoon

The following officers were elected: chairman, Dr. Rodger I. Lee, Boston; vice chairman, Dr. Norman M. Keith, Rochester, Minn.; secretary, Dr. Robert L. Levy, New York; delegate, Dr. Paul D. White, Boston; alternate, Dr. Cary Eggleston, New York; Executive Committee, Drs. Thomas Ordway, Albany, N. Y.; W. de B. MacNider, Chapel Hill, N. C., and Rodger I. Lee, Boston.

Dr. W. F. Lorenz, Madison, Wis., read a paper on "Clinical Results Obtained from Tryparsamide Therapy in Cerebrospinal Syphilis." Discussed by Drs. Carl Voegtlin, Washington, D. C.; John F. Hogan, Baltimore; Cary Eggleston, New York, and W. F. Lorenz, Madison, Wis.

Dr. Walter C. Alvarez, Rochester, Minn., read a paper on "The Treatment of 'Functional' Digestive Disturbances." Discussed by Drs. Cary Eggleston, New York; G. H. Wood, Detroit, and Walter C. Alvarez, Rochester, Minn.

Dr. Russell F. Sheldon, Boston, read a paper on "Control of Hiccup by Inhalation of Carbon Dioxide: Report of Cases." Discussed by Dr. B. C. Sword, New Haven, Conn.

Dr. C. W. Barrier, Jr., Forth Worth, Texas, read a paper on "The Use of Quinidine in Ectopic Rhythms." Discussed by Drs. Alberta Hornor, Boston; Robert F. Leinbach, Charlotte, N. C., and C. W. Barrier, Jr., Fort Worth, Texas.

Drs. Cary Eggleston, New York, and Thomas J. White, Jersey City, N. J., presented a paper on "The Absorption of Strophanthin Following Sublingual Administration." Discussed by Dr. Carl Voegtlin, Washington, D. C.

Dr. Leslie T. Gager, New York, read a paper on "The Incidence and Management of Hypertension, with a Note on Sulphocyanate Therapy." Discussed by Drs. Abraham Trasoff, Philadelphia; Norman M. Keith, Rochester, Minn., and Leslie T. Gager, New York.

SECTION ON PATHOLOGY AND PHYSIOLOGY

Wednesday, May 18—Morning

The meeting was called to order at 9:30 by the chairman, Dr. Roy G. Hoskins, Boston.

The following members were nominated for Associate Fellowship in the American Medical Association: Earl B. McKinley, New York; A. B. Bolliger, Detroit, and Allan Winter Rowe, Boston.

Roy G. Hoskins, Boston, read the chairman's address, entitled "The Relation of the Suprarenal Gland to the Sympathetic Nervous System."

Drs. A. S. Giordano, South Bend, Ind., and F. C. Mann, Rochester, Minn., presented a paper on "Observations on the Sphincter of the Choledochus." Discussed by Dr. G. E. Burget, Portland, Ore.

Dr. G. E. Burget, Portland, Ore., read a paper on "Regulation of Flow of Bile." Discussed by Drs. A. C. Ivy, Chicago; A. S. Giordano, South Bend, Ind.; Lester R. Whitaker, Boston, and G. E. Burget, Portland, Ore.

Dr. A. H. McIndoe, Rochester, Minn., read a paper on "The Vascular Lesions of Portal Cirrhosis." Discussed by Drs. Norman M. Keith, Rochester, Minn.; J. Shelton Horsley, Richmond, Va., and A. H. McIndoe, Rochester, Minn.

Drs. Frank W. Hartman, Adolph Bolliger and Howard P. Doub, Detroit, presented a paper on "The Cardiovascular Response in Experimental Nephritis." Discussed by Drs. J. W. Sherrill, La Jolla, Calif., and Frank W. Hartman, Detroit.

Drs. T. S. Moise and A. H. Smith, New Haven, Conn., presented a paper on "A Study of the Effect of the Ingestion of Excessive Amounts of Protein on the Kidneys After a Unilateral Nephrectomy in White Rats." Discussed by Dr. L. H. Newburgh, Ann Arbor, Mich.

Dr. R. L. Kahn, Lansing, Mich., read a paper on "Five Years' Application of the Kahn Test." Discussed by Drs. R. R. Gasser, Washington, D. C.; O. B. Hunter, Washington, D. C.; Frank W. Hartman, Detroit; Fred Berry, Columbus, Ohio; M. W. Lyon, Jr., South Bend, Ind.; R. A. Kilduffe, Atlantic City, N. J.; B. S. Kline, Cleveland; R. A. Keilty, Danville, Pa.; C. E. Roderick, Battle Creek, Mich.; A. J. Casselman, Camden, N. J., and R. L. Kahn, Lansing, Mich.

Thursday, May 19—Morning

The meeting was called to order at 9:30 by the chairman, who announced the following Nominating Committee: Drs. Harry J. Corper, Denver; Lloyd Arnold, Chicago, and R. G. Mills, Rochester, Minn.

Dr. Emil Bogen, Cincinnati, read a paper on "Drunkenness: A Quantitative Study of Acute Alcoholic Intoxication." Discussed by Drs. Harold L. Higgins, Cincinnati; M. W. Lyon, Jr., South Bend, Ind.; Roy G. Hoskins, Boston, and Emil Bogen, Cincinnati.

Dr. Frederick Eberson, San Francisco, read a paper on "Filtrable Toxins of the Tubercle Bacilli and the Production of Antitoxin Serum in the Sheep." Discussed by Drs. H. J. Corper, Denver; J. M. Anderson, Columbus, Ga., and Frederick Eberson, San Francisco.

Dr. H. J. Corper, Denver, read a paper on "Organic Tuberculosis in Man Analyzed from Postmortem and Experimental Data." No discussion.

Drs. William E. Cary and Lois A. Day, Chicago, presented a paper on "The Etiology of Measles." Discussed by Drs. William H. Park, New York; W. T. Harrison, Washington, D. C.; Frederick Eberson, San Francisco, and William E. Cary, Chicago.

Drs. John A. Kolmer and Malcolm J. Harkins, Philadelphia, presented a paper on "Further Investigations Bearing on Gye's Hypothesis of the Etiology of Malignant Tumors." Discussed by Dr. Francis Carter Wood, New York.

Dr. Jesse M. Bullowa and William H. Park, New York, presented a paper on "The Effect of Antipneumococcus Serum on the Leukocytes and on Bacteremia." Discussed by Drs. Alexander Lambert, New York; M. B. Rosenbluth, New York; R. A. Keilty, Danville, Pa.; Jesse M. Bullowa, New York, and William H. Park, New York.

Dr. L. W. Smith, Boston, read a paper on "The Pathology of Pertussis, with Especial Reference to Pertussis Bacillus Pneumonia." Discussed by Drs. Martha Wollstein, New York; William H. Park, New York; J. A. Kolmer, Philadelphia, and L. W. Smith, Boston.

Dr. William G. Exton, New York, read a paper on "A System for Optical Measurement and Study of Colloids and Other Dispersions." Discussed by Drs. J. A. Kolmer, Philadelphia, and Frank W. Hartman, Detroit.

Friday, May 20—Morning

The following officers were elected: chairman, Dr. H. R. Wahl, Kansas City, Mo.; vice chairman, Dr. M. H. Rees, Denver; secretary, Dr. J. J. Moore, Chicago; delegate, Dr. D. J. Davis, Chicago; alternate, Dr. J. J. Moore, Chicago.

Dr. Allan W. Rowe, Boston, read a paper on "Sugar Tolerance as an Aid to Diagnosis." Discussed by Drs. Charles H. Lawrence, Boston; H. J. John, Cleveland; Hector Mortimer, London; Roy G. Hoskins, Boston, and Allan W. Rowe, Boston.

Dr. Frederick M. Allen, Morristown, N. J., read a paper on "Physiologic and Clinical Properties of Blueberry Leaf

Extract in Relation to Carbohydrate Metabolism" Discussed by Drs J F Anderson, New Brunswick, N J, J A Morrell, New Brunswick, N. J; J W Sherrill, La Jolla, Calif and Frederick M Allen, Morristown, N J

Drs Walter Bauer and J C Aub, Boston, presented a paper on "Calcium Metabolism in Thyroid Disease" Discussed by Drs J H Means, Boston, and Walter Bauer Boston

Dr W H Howell, Baltimore, read a paper on "The Structure and Properties of Heparin" No discussion

Dr William C MacCarty, Rochester, Minn read a paper on "Chronic Splenomegalies" Discussed by Drs Ward J MacNeal, New York, and W C MacCarty Rochester, Minn

Dr Joseph C Bloodgood, Baltimore, read a paper on "The Danger of Incomplete Operations in Apparently Innocent Tumors and the Question of Tissue Examination and Diagnosis in Operating Rooms" Discussed by Dr William C MacCarty, Rochester, Minn

SECTION ON NERVOUS AND MENTAL DISEASES

WEDNESDAY, MAY 18—AFTERNOON

The meeting was called to order at 2 10 by the chairman, Dr William House, Portland, Ore

The secretary stated that Dr. Alfred Gordon, Philadelphia, who was to have presented a paper on Friday, would be unable to be present because of illness A communication from the Joint Committee of Public Health Education and the American Medical Association was then read by the secretary, who stated that part of their program was the preparation of bulletins dealing with the health of school children It was voted, on motion of Dr W A. Jones, Minneapolis, duly seconded, that the Section on Nervous and Mental Diseases consent to the appointment of a subcommittee by the chairman of the section to prepare a similar type of report to be published as a bulletin The chairman stated that the matter would be taken up with the councilors of the section and that the committee would be appointed at a later date

The secretary read communications proposing and endorsing the nomination of Prof G Mingazzini, Rome, for Honorary Fellowship in the Association, which were received from Drs William G Spiller, Philadelphia, Bernard Sachs, New York, Charles K Mills, Philadelphia, and Charles L Dana, New York Dr Walter J Freeman, Jr, Washington, D C, moved that the nomination of Professor Mingazzini for Honorary Fellowship in the American Medical Association be approved, and the motion was duly seconded and was carried unanimously

Dr William House, Portland, Ore, read the chairman's address, entitled "Some Socio Economic Problems in Neuropsychiatry"

Dr Groves B Smith, Detroit, read a paper on "The Psychoneuroses Their Problems in a General Hospital"

Dr Cornelius C Wholey, Pittsburgh, read a paper on "Mental Symptoms in Relation to General Medicine"

These two papers were discussed by Drs J M Bessey, Toledo, Edmund Jacobson, Chicago, George B Lake, Chicago, S P Goodhart, New York, W F Robie, Baldwinsville, Mass, Theodore Diller, Pittsburgh, Groves B Smith, Detroit, and Cornelius C Wholey, Pittsburgh

Dr Philip R Lehrman, New York, read a paper on "The Significance of Phantasies in Neurotic Behavior" Discussed by Drs William L Nelson, St Louis, and Philip R Lehrman, New York

Dr Joseph McIver, Philadelphia, read a paper on "The Juvenile Delinquent" Discussed by Drs Cornelius C Wholey, Pittsburgh, E J Emerick, Columbus, Ohio, William L Nelson, St Louis, and Joseph McIver, Philadelphia

Drs George W Hall, M M Kunde and F J Gerty, Chicago, presented a paper on "The Effect of Nonspecific Protein Therapy on the Blood and Cerebrospinal Fluid in General Paralysis" Discussed by Drs A L Skoog, Kansas City, Mo, T R Robie, Poughkeepsie, N Y, A B Magnus, Chicago, W F Lorenz, Madison, Wis, and George W Hall, Chicago

Dr L L Cazenavette, New Orleans, read a paper on "Mental Aspect of Leprosy" Discussed by Prof G H Monrad-Krohn of the University of Oslo, Norway, and L L Cazenavette, New Orleans

THURSDAY, MAY 19—AFTERNOON

Dr Charles H Frazier, Philadelphia, read a paper on "Fourteen Years Experience with Fractional Section of Sensory Root as the Major Operation in Trigeminal Neuralgia" Discussed by Drs William H Riley, Battle Creek Mich, William House, Portland, Ore, and Charles H Frazier, Philadelphia

Drs Howard W Fleming and Howard C Naffziger, San Francisco, presented a paper on "Physiology and Treatment of Transient Hemiplegia" Discussed by Drs Walter J Freeman, Jr, Washington, D C, I Leon Meyers, Los Angeles, Lewis J Pollock, Chicago, and Howard C Naffziger, San Francisco

Dr Walter J Freeman, Jr, Washington, D C, read a paper on "The Treatment of Encephalitis" Discussed by Drs George W Hall, Chicago, A L Skoog, Kansas City, Mo, W F Lorenz, Madison, Wis, E C Rosenow, Rochester Minn, Harry Alton Schachter, Newark, N J, L L Cazenavette, New Orleans, H S Hulbert, Chicago, William House, Portland, Ore, and Walter J Freeman, Jr, Washington, D C

Dr Irving J Sands, Brooklyn, read a paper on "The Acute Psychiatric Type of Epidemic Encephalitis" Discussed by Drs Walter J Freeman, Jr, Washington, D C, Theodore T Stone, Chicago, Harry Alton Schachter, Newark, N J, and Irving J Sands, Brooklyn

Dr Edward C Rosenow, Rochester, Minn, read a paper on "Further Studies on the Etiologic Relationship of Streptococci to Epidemic Encephalitis, Epidemic Hiccup, Spasmodic Torticollis and Chorea" Discussed by Drs A L Skoog, Kansas City, Mo, Walter J Freeman, Jr, Washington, D C, Peter Bassoe, Chicago, and Edward C Rosenow, Rochester, Minn

Dr Eugene S Kilgore, San Francisco, read a paper on "The Measurement of Cerebrospinal Fluid Pressure" Discussed by Drs J J Sampson, San Francisco, J B Ayer, Boston, and Eugene S Kilgore, San Francisco

The chairman appointed Drs Peter Bassoe, Chicago, and James B Ayer, Boston, to act with the Executive Committee and approve papers

FRIDAY, MAY 20—AFTERNOON

The following officers were elected chairman, Dr Lewis J Pollock, Chicago, vice chairman, Dr John L Eckel, Buffalo, secretary, Dr Walter J Freeman, Jr, Washington, D C, delegate, Dr Tom B Throckmorton, Des Moines, Iowa, alternate, Edward Delehanty, Denver

The delegate, Dr Tom B Throckmorton, Des Moines, Iowa, gave a report on the activities of the House of Delegates, which was accepted by the section

Drs Edward Livingston Hunt and James R Lisa, New York, presented a paper on "A Case of Frontal Lobe Tumor Simulating Epidemic Encephalitis, with Parkinson's Syndrome" Discussed by Drs Tom B Throckmorton, Des Moines, Iowa, Walter J Freeman, Jr, Washington, D C, A B Magnus, Chicago, William House, Portland, Ore, and James R Lisa, New York

Dr I Leon Meyers, Los Angeles, read a paper on "Cerebellar Phenomena in Lesions of the Temporal Lobe" Discussed by Drs S D Ingham, Los Angeles, A B Magnus, Chicago, James B Ayer, Boston, and I Leon Meyers, Los Angeles

Dr H H Drysdale, Cleveland, read a paper on "Acute Circumscribed Edema (Quincke)" Discussed by Drs Peter Bassoe, Chicago Theodore T Stone, Chicago, George W Hall, Chicago, Harry Alton Schachter, Newark, N J, and H H Drysdale, Cleveland

Dr Glenville Giddings, Atlanta, read a paper on "Friedreich's Ataxia in Nine Members of a Family" Discussed by Drs A L Skoog, Kansas City, Mo, and Glenville Giddings, Atlanta, Ga

SECTION ON DERMATOLOGY AND SYPHILOLOGY

Wednesday, May 18—Afternoon

The meeting was called to order at 2:15 by the chairman, Dr. James Herbert Mitchell, Chicago.

Dr. Mitchell called attention to the scientific exhibit from the section and announced that Dr. Howard Fox had been awarded a certificate of merit. He then requested Dr. F. D. Weidman to report for the Committee on Exhibit, as Chairman.

Dr. Weidman reported that there had been considerable work in connection with arranging the exhibit and securing proper material, and that much of the credit for the success of the exhibit was due the local member of the committee, Dr. F. J. Eichenlaub, and Dr. Clark W. Finnerud. This was the third year the section had had a successful exhibit, and the committee wished an expression of opinion as to whether it should be continued, which would necessitate a contribution from the members of the section to defray the necessary expenses. The appointment of the chairman of the committee had always been made by the chairman of the section, and he felt all would agree that three years in this position was sufficient for any one.

Dr. William Allen Pusey moved that the exhibit be continued, and that the members of the section have it suggested to them that a contribution of $5 each for defraying the expenses of the exhibit would be acceptable.

Motion seconded by several and unanimously carried.

The chairman appointed Drs. Eichenlaub and Finnerud to collect this fund.

Dr. Howard Fox introduced the guest of the section, Dr. L. M. Pautrier of Strasbourg, and moved that Dr. Pautrier be recommended for Honorary Membership in the American Medical Association.

Motion seconded and unanimously carried.

Dr. William Allen Pusey requested the privilege of the floor, and said: Intimations have been given from various quarters that it might be desirable to invite the dermatologists of the world to come to the United States within the next two or three years for an international dermatologic congress. At the recent meeting of the American Dermatological Association a motion was passed that a committee of nine be appointed from that organization which should invite this section of the American Medical Association to appoint a committee of the same number, these two groups to form a joint committee of eighteen, the committee of nine to be selected by the chairman. This committee should elect its chairman, and then consider in the next year the question of holding an international dermatologic congress in the United States, probably in 1930, each of these committees to report back the conclusions of the joint committee to their respective associations at their meetings in 1928.

I move that the Section on Dermatology and Syphilology of the American Medical Association approve the appointment of a committee of nine to act with a similar committee of nine from the American Dermatological Association as a joint committee to consider an international dermatologic congress and report back in 1928.

I have asked the authorities of the American Medical Association if such action on the part of this section would be legal and have been informed that it would be entirely so.

Motion seconded.

Dr. Pusey's motion was then put to a vote and unanimously carried.

Dr. Harold N. Cole, Cleveland, presented the following report of the Committee on Furs, Hair Dyes and Cosmetics:

Your Committee on Furs, Hair Dyes and Cosmetics was appointed by the Chairman of this Section, at the request of the Board of Trustees, to cooperate with the Bureau of Legal Medicine and Legislation in efforts to carry out the resolution passed by the House of Delegates in May, 1924, as follows:

> Whereas, There has lately been an enormous increase in the use of cosmetics; and
>
> Whereas, Many of these cosmetics contain chemicals irritating and even dangerous to the human organism; and
>
> Whereas, The dye paraphenylendiamine has so often resulted in serious and even in dangerous irritation when employed in furs or on human hair; be it
>
> *Resolved*, That the Section on Dermatology and Syphilology, through its regularly appointed Executive Committee, urgently recommend to the favorable attention of the American Medical Association (1) that they foster legislation placing cosmetic preparations under the Food and Drugs Act, and especially requiring the placing of the names of all poisonous ingredients on the labels; (2) that they foster legislation prohibiting the use of the most harmful types of ingredients in cosmetics; (3) that they foster legislation to prohibit the use of paraphenylendiamine as a dye for hair and fur; and that the American Medical Association urge laws with criminal liability to enforce the recognition of these demands.

As the result of questionnaires sent out by your committee, of certain syndicated articles in the public press, of a request published in The Journal for reports of cases and of an article by the chairman of your committee, published in The Journal, Feb. 5, 1927, reports of 447 cases of injuries from hair dyes, dyed furs and cosmetics have been received. One hundred and forty-four injuries from dyed fur were reported by physicians and fifty-five by laymen, the latter being unsupported by medical evidence. Physicians reported 111 cases of injury from hair dyes, and 137 from cosmetics. In addition to these, physicians reported fifty-six cases of injuries from dyed clothing, thirty-four from hair tonics and twenty-seven from miscellaneous preparations, including deodorants, depilatories and toilet waters.

Your committee has corresponded with representatives of the Association of Dairy, Food and Drug Officials with respect to legislation proposed by that organization. A bill to regulate the sale of "cosmetics" was submitted to your committee by that association, through the Bureau of Legal Medicine and Legislation, and suggestions were offered by your committee. Some of these suggestions were accepted, some rejected, and the bill was approved by the association named at its annual convention held in Washington in October, 1926. In this bill the term "cosmetic" is defined to mean any substance or combination of substances represented, as for use externally or by direct application for embellishing, cleansing, perfuming, conditioning or otherwise improving the appearance of the skin, lips, eyes, hair, nails or teeth of the human body, whether with or without reference to the cure, mitigation or prevention of disease; except (*a*) substances prescribed or applied for any purpose named above by regularly licensed doctors of medicine and doctors of dental surgery for patients whom they are personally attending, and (*b*) substances and mixtures of substances bearing only names recognized in the U. S. Pharmacopeia, or in the National Formulary, and without claims for remedial value. Legislation based on this bill was introduced in 1927 in Massachusetts, Connecticut, Maine and New Hampshire but failed to pass.

For the purpose of increasing the interest of physicians in the pending movement, the Bureau of Investigation of the American Medical Association, at the suggestion of your committee and in cooperation with it, prepared an exhibit for the Washington session. It is suggested that the posters comprising this exhibit contain much of value and physicians are urged to study them.

Work has been done toward drafting legislation to carry out the resolution of the House of Delegates set forth above, but no final agreement has been reached concerning it.

We might add that this movement has also been recently endorsed by the American Dermatological Association through the appointment of this same committee from its members, Drs. Senear, Wile and Cole, and through the giving to this committee of power to act.

Respectfully submitted,

Francis E. Senear.
Udo J. Wile.
H. N. Cole, Chairman.

Whereas, The Committee on Cosmetics of the Section on Dermatology and Syphilology has conducted an investigation in regard to the evils resulting from the use of certain hair dyes, dyed furs and cosmetics; and

Whereas, Said Committee has been studying proposed legislation to curb such evils and is cooperating with a like committee from the American Dermatological Association; therefore, be it

Resolved, That the Section on Dermatology and Syphilology through its delegate does hereby submit this question to the House of Delegates for further action.

Francis E. Senear.
Udo J. Wile.
Harold N. Cole, Chairman.

Dr. William H. Guy, Pittsburgh, moved that the report be accepted and referred to the section delegate for presentation to the House of Delegates of the American Medical Association for action.

Motion seconded and unanimously carried.

Dr. James Herbert Mitchell, Chicago, read the chairman's address, entitled "Need for Research in the Treatment of Epidermophytoses."

Drs. Herman Sharlit and Walter James Highman, New York, presented a paper on "The Use of Tetraiodomethenamine in Flexible Collodion in the Treatment of Dermatophytosis."

Karl L. Karrenberg, Hamburg, Germany, read a paper on "Present State and Frequency of Epidermophytosis in Europe."

These two papers were discussed by Drs. Frederick D. Weidman, Philadelphia; T. Caspar Gilchrist, Baltimore; Harold N. Cole, Cleveland; Howard J. Parkhurst, Toledo, Ohio; Everett S. Lain, Oklahoma City; F. J. Eichenlaub, Washington, D. C.; Moses Scholtz, Los Angeles; Joseph Müller, Holden, Mass.; Walter James Highman, New York, and Herman Sharlit, New York.

Dr. L. M. Pautrier, Strasbourg, read a paper on "Paget's Disease of the Nipple not a Precancerous Stage but an Epidermoid Cancer Demanding Early Removal of the Breast." Discussed by Drs. Udo J. Wile, Ann Arbor, Mich.; Jay Frank Schamberg, Philadelphia, and T. Caspar Gilchrist, Baltimore.

Dr. Udo J. Wile, Ann Arbor, Mich., read a paper on "Further Studies on Bromide Intoxication." Discussed by Drs. George H. Belote, Ann Arbor, Mich.; William H. Guy, Pittsburgh; Harold N. Cole, Cleveland; Joseph J. Eller, New York; Paul E. Bechet, New York; Lester Hollander, Pittsburgh; Everett S. Lain, Oklahoma City, and Udo J. Wile, Ann Arbor, Mich.

Drs. Henry H. Whitehouse and Paul E. Bechet, New York, presented a paper on "The Treatment of Lupus Erythematosus, Lupus Vulgaris, the Tuberculids and Tuberculosis of the Skin with Gold Compounds." Discussed by Drs. Jay Frank Schamberg, Philadelphia; Howard Fox, New York; Jeffrey C. Michael, Houston, Texas; Joseph J. Eller, New York; Paul A. O'Leary, Rochester, Minn.; Adolph Rostenberg, New York; Jacob Edgar Fisher, Cleveland; Harry C. Saunders, New York, and Paul E. Bechet, New York.

Drs. Joseph V. Klauder and N. W. Winkelman, Philadelphia, presented a paper on "Pellagra Among Chronic Alcoholics." Discussed by Drs. Howard Fox, New York; Jay Frank Schamberg, Philadelphia; Everett S. Lain, Oklahoma City; Earl D. Crutchfield, Galveston, Texas; Joseph N. Roussel, New Orleans; J. B. Shelmire, Dallas, Texas, and J. V. Klauder, Philadelphia.

Dr. Francis Lowell Burnett, Boston, read a paper on "The Control of Health after Eczema and Psoriasis." Discussed by Drs. William H. Robey, Jr., Boston; Walter J. Highman, New York; Joseph J. Eller, New York, and Francis L. Burnett, Boston.

Thursday, May 19—Afternoon

Dr. Mitchell announced the appointment of the following as a committee from the Section on Dermatology and Syphilology to serve with a like committee from the American Dermatological Association to consider the feasibility of an international dermatologic congress: Dr. George Miller MacKee, New York; Dr. Fred Wise, New York; Dr. Howard Morrow, San Francisco; Dr. T. Caspar Gilchrist, Baltimore; Dr. Martin F. Engman, St. Louis; Dr. C. Morton Smith, Boston; Dr. John E. Lane, New Haven, Conn.; Dr. Harold N. Cole, Cleveland, and Dr. Frank W. Cregor, Indianapolis, and the first meeting of this committee to be held at 9 p. m. at the Mayflower Hotel.

The chairman further announced that through some error the collection that was authorized to defray the expenses of the Scientific Exhibit was not made on Wednesday, and appointed Drs. Jeffrey C. Michael and Howard J. Parkhurst to make the collection at this time.

Dr. Lester Hollander, Pittsburgh, read a paper on "Organic Luetin: Its Use in the Diagnosis of Syphilis." Discussed by Drs. John A. Kolmer, Philadelphia; John H. Stokes, Philadelphia, and Lester Hollander, Pittsburgh.

Dr. Paul A. O'Leary, Rochester, Minn., read a paper on "The Third Year Results with Malaria Therapy of Neurosyphilis." Discussed by Drs. Harold N. Cole, Cleveland; Udo J. Wile, Ann Arbor, Mich.; Watson William Eldridge, Jr., Washington, D. C.; J. E. Moore, Baltimore, and Paul A. O'Leary, Rochester, Minn.

Dr. George H. Belote, Ann Arbor, Mich., read a paper on "Pregnancy and Neurosyphilis." Discussed by Drs. J. E. Moore, Baltimore; John H. Stokes, Philadelphia, and George H. Belote, Ann Arbor, Mich.

Drs. John H. Stokes and Stanley O. Chambers, Philadelphia, presented a paper on "Clinical Observations on Bismuth Arsphenamine Sulphonate in the Treatment of Syphilis." Discussed by Drs. George W. Raiziss, Philadelphia; Paul A. O'Leary, Rochester, Minn.; Harold N. Cole, Cleveland; Joseph Muller, Holden, Mass., and John H. Stokes, Philadelphia.

Drs. Harold N. Cole, John A. Gammel, John A. Rauschkolb, Nora Schreiber and Torald Sollmann, Cleveland, presented a paper on "The Clinical Excretion of Mercury After Intramuscular Injections and Inunctions." Discussed by Drs. Frederick M. Jacob, Pittsburgh; F. J. Eichenlaub, Washington, D. C.; John H. Stokes, Philadelphia, and Harold N. Cole, Cleveland.

Dr. Carroll S. Wright, Philadelphia, read a paper on "Bismuth in the Treatment of Congenital Syphilis." Discussed by Drs. Joseph G. Hopkins, New York; Joseph J. Eller, New York; John H. Stokes, Philadelphia, and Carroll S. Wright, Philadelphia.

Dr. A. Benson Cannon, New York, read a paper on "The Prognosis of Congenital Syphilis." Discussed by Drs. Udo J. Wile, Ann Arbor, Mich.; Joseph G. Hopkins, New York; A. W. Nelson, Cincinnati, and A. Benson Cannon, New York.

Friday, May 20—Afternoon

The following officers were elected: chairman, Dr. Udo J. Wile, Ann Arbor, Mich.; vice chairman, Dr. Samuel E. Sweitzer, Minneapolis; secretary, Dr. William H. Guy, Pittsburgh; delegate, Dr. Howard Fox, New York; alternate, Dr. Otto H. Foerster, Milwaukee.

The chairman presented a letter from Dr. John Milton Dodson concerning the appointment of a standing Committee on Health Problems in Education, such committee to consist of three members, to meet with similar committees from other sections and the committee from the National Educational Association.

Dr. John E. Lane moved that the chairman be empowered to appoint such a committee.

Motion seconded and unanimously carried.

The chairman appointed the following to serve as this committee: Dr. Harry G. Irvine, Minneapolis, chairman; Dr. C. Guy Lane, Boston, and Dr. Otto H. Foerster, Milwaukee.

Dr. E. B. Tauber, Cincinnati, read a paper on "Cosmetics and Their Relation to Dermatology." Discussed by Drs. Harold N. Cole, Cleveland; William Allen Pusey, Chicago; George M. MacKee, New York; Lawrence K. McCafferty, New York; John E. Lane, New Haven, Conn.; C. Guy Lane, Boston; F. J. Eichenlaub, Washington, D. C.; T. Caspar Gilchrist, Baltimore; William H. Guy, Pittsburgh; C. F. Lehman, San Antonio, Texas; Jeffrey C. Michael, Houston, Texas; M. A. Killeen, Dubuque, Iowa; Paul E. Bechet, New York; James Herbert Mitchell, Chicago, and E. B. Tauber, Cincinnati.

Drs. J. J. Eller and Gustav Bucky, New York, presented a paper on "The 'Grenz' (Infra-Roentgen) Rays in Dermatology: Preliminary Report of Clinical and Biologic Observations." Discussed by Drs. George M. MacKee, New York; Edward R. Maloney, New York; Jeffrey C. Michael, Houston, Texas; Charles Lerner, New York; T. Caspar Gilchrist, Baltimore; William Allen Pusey, Chicago; William H. Guy, Pittsburgh; Gustav Bucky, New York, and J. J. Eller, New York.

Dr. Sigmund S. Greenbaum, Philadelphia, read a paper on "Blood Calcium in the Urticarias." Discussed by Drs. Udo J. Wile, Ann Arbor, Mich.; Paul A. O'Leary, Rochester, Minn.; Everett S. Lain, Oklahoma City; William Allen Pusey, Chicago, and Sigmund S. Greenbaum, Philadelphia.

Dr. Marvin D. Shie, Cleveland, read a paper on "A Study of Tattooing and Methods of Its Removal." Discussed by Drs. Harold N. Cole, Cleveland; William Allen Pusey, Chicago, and Marvin D. Shie, Cleveland.

Dr. Arthur M. Greenwood, Boston, read a paper on "A Study of the Skin in Five Hundred Cases of Diabetes." Discussed by Drs. C. Guy Lane, Boston, and Arthur M. Greenwood, Boston.

Dr. A. R. McFarland, Rochester, N. Y., read a paper on "The Use of Gentian Violet Preparations in Diseases of the Skin." Discussed by Drs. John H. Stokes, Philadelphia; Dudley C. Smith, University, Va.; Jeffrey C. Michael, Houston, Texas; Robert V. Hoffman, South Bend, Ind.; Moses Scholtz, Los Angeles; William J. MacDonald, Boston; C. F. Lehman, San Antonio, Texas; Harold N. Cole, Cleveland, and A. R. McFarland, Rochester, N. Y.

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

Wednesday, May 18—Morning

The meeting was called to order at 9 o'clock by the chairman, Dr. W. F. Draper, Washington, D. C.

Dr. William A. Sawyer, Rochester, N. Y., read a paper on "Relations of Industrial Medical Departments to Community Health Programs." Discussed by Drs. Lloyd Noland, Fairfield, Ala.; L. W. Corbett, Goldsboro, N. C.; F. L. Rector, Chicago; G. H. Wood, Detroit; Volney S. Cheney, Chicago; S. W. Welch, Montgomery, Ala.; Joseph S. Lawrence, Albany, N. Y., and William A. Sawyer, Rochester, N. Y.

Dr. W. F. Draper, Washington, D. C., read the chairman's address, entitled "The Unexplored Field of Preventive Medicine in Private Practice."

Drs. W. S. Leathers and Hugh J. Morgan, Nashville, Tenn., presented a paper on "A Study of Lead Poisoning in an Enameling Plant." Discussed by Drs. A. J. Lanza, New York; Haven Emerson, New York; Louis I. Harris, New York; E. F. Smith, Swissvale, Pa., and W. S. Leathers, Nashville, Tenn.

Dr. J. P. Leake, Washington, D. C., read a paper on "Lead Hazards." Discussed by Drs. Albert J. Chesley, St. Paul, and Haven Emerson, New York.

Dr. Henry Albert, Des Moines, read a paper on "Reasons for the Increasing Mortality from Heart Disease." Discussed by Drs. Haven Emerson, New York; L. F. Bishop, New York; Eugene L. Fisk, New York; M. M. Myers, Des Moines, and Henry Albert, Des Moines.

Thursday, May 19—Morning

Dr. Lloyd Arnold, Chicago, read a paper on "Host Susceptibility to Typhoid, Dysentery, Diarrhea and Food Poisoning." Discussed by Drs. Haven Emerson, New York; G. H. Wood, Detroit, and Lloyd Arnold, Chicago.

Drs. H. C. Stewart and William Litterer, Nashville, Tenn., presented a paper on "Dyersburg Epidemic." Discussed by Drs. Kenneth F. Maxcy, Washington, D. C.; Lloyd Arnold, Chicago; H. C. Stewart, Nashville, Tenn., and William Litterer, Nashville, Tenn.

Dr. D. G. Gill, Montgomery, Ala., read a paper on "The Epidemiology of Rural Typhoid." Discussed by Drs. S. W. Welch, Montgomery, Ala.; H. G. Grant, Richmond, Va.; R. H. Riley, Baltimore; Edward S. Godfrey, Jr., Albany, N. Y.; H. C. Stewart, Nashville, Tenn., and D. G. Gill, Montgomery, Ala.

Dr. W. G. Smillie, New York, read a paper on "The Future of County Health Work." Discussed by Drs. W. K. Sharp, Nashville, Tenn.; Lacy W. Corbett, Goldsboro, N. C.; L. L. Lumsden, Washington, D. C.; S. W. Welch, Montgomery, Ala.; John A. Ferrell, New York, and W. G. Smillie, New York.

Dr. John E. Monger, Columbus, Ohio, read a paper on "Progress and Status of Local Health Work in Ohio."

Dr. C. H. O'Laughinghouse, Raleigh, N. C., read a paper on "Critical Analysis of County Health Work."

These two papers were discussed by Drs. John A. Ferrell, New York; E. A. Hines, Seneca, S. C., and J. A. Hayne, Columbia, S. C.

Friday, May 20—Morning

The following officers were elected: chairman, Dr. Louis I. Harris, New York; vice chairman, Dr. Charles N. Leach, Montgomery, Ala.

Dr. Haven Emerson, New York, read a paper on "Seasonal Variation in Growth of Children." No discussion.

Dr. Henry D. Chadwick, Westfield, Mass., read a paper on "Observations in the Underweight Clinics in the Schools of Massachusetts." No discussion.

Dr. Frank L. Roberts, Trenton, Tenn., read a paper on "The Growth of Children That Are Below Average Weight." Discussed by Drs. Haven Emerson, New York; Henry D. Chadwick, Westfield, Mass.; Seneca Egbert, Philadelphia, and Frank L. Roberts Trenton, Tenn.

SECTION ON UROLOGY

Wednesday, May 18—Morning

The meeting was called to order at 9:10 by the chairman, Dr. George Gilbert Smith, Boston.

Dr. C. W. Collings, New York, read a paper on "Electrotome Excision of Prostatic Bar." Discussed by Drs. Alexander Randall, Philadelphia; E. L. Keyes, New York; George R Livermore, Memphis, Tenn.; A. E. Mackay, Portland, Ore.; Edwin Beer, New York; B. S. Barringer, New York, and C. W. Collings, New York.

The chairman appointed Dr. Robert V. Day, Los Angeles, to serve on the Executive Committee, in the place of Dr. John T. Geraghty, deceased.

Dr. A. L. Dean, Jr., New York, read a paper on "Ulceration of the Urinary Bladder as a Late Effect of Radium Applications to the Uterus." Discussed by Drs. E. L. Keyes, New York; John H. Cunningham, Boston; B. S. Barringer, New York; Clarence G. Bandler, New York; Edwin Beer, New York; George Gilbert Smith, Boston; Oscar L. Norsworthy, Houston, Texas; J. W. Barson, Joplin, Mo.; Herman L. Kretschmer, Chicago, and A. L. Dean, Jr., New York.

The following papers were read as a symposium on "The Treatment of Bladder Neoplasm":

Dr. E. L. Keyes, New York: "Principles Governing the Local Treatment of Bladder Carcinoma."

Drs. H. L. Kretschmer and K. E. Barber, Chicago: "Changes in the Bladder Following Resection: An Experimental Study."

Dr. B. S. Barringer, New York: "End-Results of Radium Removal of Carcinoma of the Bladder."

These three papers were discussed by Drs. Edwin Beer, New York; Waltman Walters, Rochester, Minn.; Gilbert J. Thomas, Minneapolis; George A. Wyeth, New York; B. C. Corbus, Chicago; D. N. Eisendrath, Chicago; Bransford Lewis, St. Louis; B. A. Thomas, Philadelphia; John H. Cunningham, Boston; Hermon C. Bumpus, Rochester, Minn.; E. L. Keyes, New York, and B. S. Barringer, New York.

Thursday, May 19—Morning

Dr. George Gilbert Smith, Boston, read the chairman's address, entitled "The Circulation as a Factor in Prostatic Surgery."

Dr. W. E. Lower, Cleveland, read a paper on "Complete Closure of the Bladder Following Prostatectomy." Discussed by Drs. A. L. Chute, Boston; Gilbert J. Thomas, Minneapolis; Bransford Lewis, St Louis; Henry J. Scherck, St. Louis; Alexander Randall, Philadelphia; William C. Fowler, Washington, D. C.; C. W. Collings, New York, and W. E. Lower, Cleveland.

Dr. J. H. Morrissey, New York, read a paper on "Seminal Vesicle and Prostatic Foci in Pelvic, Perirectal and Ischiorectal Suppuration in Males." Discussed by Drs. Leon Herman, Philadelphia; Jerome M. Lynch, New York; Bransford Lewis, St. Louis; D. N. Eisendrath, Chicago; Ralph W. Jackson, Fall River, Mass.; John H. Cunningham, Boston, and J. H. Morrissey, New York.

Dr. W. G. Shultz, Tucson, Ariz., read a paper on "Heliotherapy in Genito-Urinary Tuberculosis." Discussed by Drs. Gilbert J. Thomas, Minneapolis, and W. G. Shultz, Tucson, Ariz.

Dr. D. N. Eisendrath, Chicago, read a paper on "The Value of the Inlying Ureteral Catheter in the Treatment of Acute and Chronic Pyelonephritis."

Dr. B. C. Corbus, Chicago, read a paper on "Pyelonephritis and Its Relation to Nongonorrheal Urethritis."

Dr. G. W. Belcher, Cleveland, read a paper on "Renal Distortion."

These three papers were discussed by Drs. A. H. Crosbie, Boston; Henry J. Scherck, St. Louis; Theodore Baker, Pittsburgh; Edward L. Merritt, Fall River, Mass.; George R. Livermore, Memphis, Tenn.; Hermon C. Bumpus, Jr., Rochester, Minn.; Herman L. Kretschmer, Chicago; A. W. Nelson, Cincinnati; R. Arthur Hooe, Washington, D. C.; D. N. Eisendrath, Chicago, and B. C. Corbus, Chicago.

Friday, May 20—Morning

The following officers were elected: chairman, Dr. Frank Hinman, San Francisco; vice chairman, Dr. R. Arthur Hooe, Washington, D. C.; secretary, Dr. Hermon C. Bumpus, Jr., Rochester, Minn.; delegate, Dr. A. L. Chute, Boston; alternate, Dr. C. E. Burford, St. Louis.

Drs. B. H. Hager and T. B. Magath, Rochester, Minn., presented a paper on "Observations on the Formation of Vesical Calculi." Discussed by Drs. F. T. Lau, New York; R. Campbell Begg, Wellington, New Zealand, and B. H. Hager, Rochester, Minn.

Dr. O. S. Lowsley, New York, read a paper on "Relief of Congenital Incontinence of Urine by Operation." Discussed by Drs. R. E. Cumming, Detroit; D. K. Rose, St. Louis; R. Campbell Begg, Wellington, New Zealand, and Oswald S. Lowsley, New York.

Drs. W. T. Belfield and H. C. Rolnick, Chicago, presented a paper on "Observations on the Physiology and Therapy of the Seminal Duct."

Dr. M. F. Campbell, New York, read a paper on "Treatment of Epididymitis—Observation in Three Thousand Cases."

These two papers were discussed by Drs. J. F. McCarthy, New York; J. Sydney Ritter, New York; B. C. Corbus, Chicago; John F. Hogan, Baltimore; Francis R. Hagner, Washington, D. C.; George R. Livermore, Memphis, Tenn.; Robert H. Herbst, Chicago; H. C. Rolnick, Chicago, and M. F. Campbell, New York.

Dr. W. C. Quinby, Boston, read a paper on "Plastic Surgery of Renal Pelvis." Discussed by Drs. Thomas D. Moore, Memphis, Tenn.; D. N. Eisendrath, Chicago; Gilbert J. Thomas, Minneapolis; George Gilbert Smith, Boston; Robert H. Herbst, Chicago, and W. C. Quinby, Boston.

Drs. Robert V. Day, Los Angeles, and C. S. Vivian, Phoenix, Ariz., presented a paper on "Congenital Obstruction of the Posterior Urethra." Discussed by Drs. O. S. Lowsley, New York; Henry J. Scherck, St. Louis; Francis R. Hagner, Washington, D. C.; J. F. McCarthy, New York, and Robert V. Day, Los Angeles.

SECTION ON ORTHOPEDIC SURGERY

Wednesday, May 18—Morning

The meeting was called to order at 9:20 by the chairman, Dr. J. P. Lord, Omaha.

The following papers were read as a symposium on "Fractures":

Dr. Charles L. Scudder, Boston: "Indications for Operative Treatment."

Mr. Walter Rowley Bristow, London: "Influence of War Surgery on Treatment of Fractures in Great Britain."

Dr. Joseph Blake, New York: "Traction and Suspension."

Dr. Kellogg Speed, Chicago: "Fracture of the Shaft of the Femur: Diagnosis and Treatment."

These four papers were discussed by Drs. William O'Neill Sherman, Pittsburgh; W. L. Estes, Bethlehem, Pa.; Willis C. Campbell, Memphis, Tenn.; William Darrach, New York; Edwin W. Ryerson, Chicago; W. S. Baer, Baltimore; Joseph Blake, New York, and Kellogg Speed, Chicago.

Thursday, May 19—Morning

Dr. J. Archer O'Reilly, St. Louis, read a paper on "Abnormalities of the Lower Back." Discussed by Drs. R. E. Humphries, New York; Frank R. Ober, Boston; Samuel Kleinberg, New York; C. A. Stone, St. Louis; E. S. Johnson, Boston, and J. Archer O'Reilly, St. Louis.

Dr. George E. Bennett, Baltimore, read a paper on "Unusual Cases of Tumor of the Spinal Cord." Discussed by Drs. Edwin W. Ryerson, Chicago; A. W. Adson, Rochester, Minn.; R. V. Funston, Detroit; J. W. Sever, Boston, and George E. Bennett, Baltimore.

Dr. Edwin W. Ryerson, Chicago, read a paper on "Laminectomy: An Analysis of Operations Performed for Various Lesions." Discussed by Drs. D. B. Phemister, Chicago; George E. Bennett, Baltimore; A. W. Adson, Rochester, Minn.; Harry E. Mock, Chicago; H. W. Orr, Lincoln, Neb.; A. L. Lockwood, Toronto and Edwin W. Ryerson, Chicago.

Dr. J. P. Lord, Omaha, read the chairman's address, entitled "Factors in the Advancement of Orthopedic Surgery."

Dr. Frank R. Ober, Boston, read a paper on "Scoliosis." Discussed by Drs. Albert H. Freiberg, Cincinnati; F. J. Gaenslen, Milwaukee; George E. Bennett, Baltimore; Samuel Kleinberg, New York, and Frank R. Ober, Boston.

Dr. Armitage Whitman, New York, read a paper on "A Variation in the Operative Treatment for Structural Scoliosis." Discussed by Drs. H. W. Orr, Lincoln, Neb.; Samuel Kleinberg, New York; Edwin W. Ryerson, Chicago; Willis C. Campbell, Memphis, Tenn., and Armitage Whitman, New York.

Dr. F. J. Gaenslen, Milwaukee, read a paper on "Sacro-Iliac Arthrodesis: Author's Technic, Indication and Late Results." Discussed by Drs. Armitage Whitman, New York; R. V. Funston, Detroit and F. J. Gaenslen, Milwaukee.

Friday, May 20—Morning

The following officers were elected: chairman, Dr. James Archer O'Reilly, St. Louis; vice chairman, Dr. Walter G. Stern, Cleveland; secretary, Dr. H. W. Meyerding, Rochester, Minn.; delegate, Dr. F. J. Gaenslen, Milwaukee; alternate, Dr. Frank R. Ober, Boston.

Three resolutions were adopted by the section: 1. A resolution of appreciation to Surgeon General Ireland, Lieutenant Colonel Keller and Major Metane for their cooperation and assistance in the preparation of the fracture exhibit, with instructions to the secretary to write these gentlemen to that effect. 2. A resolution of thanks to the members of the Fracture Committee and the Advisory Committee for their untiring efforts and success in presenting a most instructive fracture exhibit and a most interesting program, with instructions to the secretary to convey these sentiments to the members of these committees. 3. A resolution expressing the desire of the section that the Fracture Committee be continued, in order to complete the work which it has so efficiently begun.

Dr. W. B. Carrell, Dallas, Texas, read a paper on "Recurring Dislocation of the Shoulder." Discussed by Drs. F. J. Cotton, Boston; Fred H. Albee, New York; T. Turner Thomas, Philadelphia; Edwin W. Ryerson, Chicago; J. W. Sever, Boston; J. T. Rugh, Philadelphia, and W. B. Carrell, Dallas, Texas.

Dr. B. A. Thomas, Philadelphia, read a paper on "Gonorrheal Arthritis." Discussed by Drs. D. P. Willard, Philadelphia; Albert H. Freiberg, Cincinnati; Richard Kovacs, New York, and B. A. Thomas, Philadelphia.

Dr. Albert H. Freiberg, Cincinnati, read a paper on "The Relationship of Physical Therapy to Orthopedic Surgery." Discussed by Drs. J. W. Sever, Boston, H. W. Orr, Lincoln, Neb.; D. P. Willard, Philadelphia; H. D. Corbusier, Plainfield, N. J.; Richard Kovacs, New York; Roland Hammond, Providence, R. I., and Albert H. Freiberg, Cincinnati.

Dr. Arthur B. Gill, Philadelphia, read a paper on "Fusion Operations on the Foot." Discussed by Drs. Fred H. Albee, New York; J. O. Wallace, Pittsburgh; Willis C. Campbell, Memphis, Tenn.; Frank R. Ober, Boston, and Arthur B. Gill, Philadelphia.

Dr. R. Plato Schwartz, Rochester, N. Y., read a paper on "A Method for Making Graphic Records of Normal and Pathologic Gait, with Description of a New Apparatus." Discussed by Drs. H. W. Orr, Lincoln, Neb.; E. G. Brackett, Boston; Charlton Wallace, New York; Albert H. Freiberg, Cincinnati; and R. Plato Schwartz, Rochester, N. Y.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

Wednesday, May 18—Afternoon

The meeting was called to order at 2 o'clock by the chairman, Dr Jerome M Lynch, New York

Dr M I Bierman, Washington, D C, read a paper on 'Intestinal Stasis Functional Types" Discussed by Drs Walter C Alvarez, Rochester, Minn , Russell S Boles, Philadelphia, G S Hanes, Louisville, Ky , Zachary Sagal, New York, E. G Martin, Detroit, and M I Bierman, Washington, D C

Dr A F R Andresen, Brooklyn, read a paper on 'Treatment of Gastric Hemorrhage" Discussed by Drs J Russell Verbrycke, Jr, Washington, D C , Donald C Balfour, Rochester, Minn , Frank Smithies, Chicago, and A F R Andresen, Brooklyn

Dr Max Einhorn, New York read a paper on "Apparent Hour-Glass Stomach, Cured by Medical Means" Discussed by Drs B B Crohn, New York I R Jankelson, Boston, J C Bloodgood, Baltimore, D C Balfour Rochester, Minn , I O Palefski New York, and Max Einhorn, New York

Dr Louis J Hirschman, Detroit read a paper on 'Enemas—Some Uses and Abuses ' Discussed by Drs G S Hanes, Louisville Ky , D C McKenney, Buffalo, and Louis J. Hirschman, Detroit

Dr W M James, Panama, R P, read a paper on 'Intestinal Amebiasis in Man, with Especial Reference to Its Diagnosis ' Discussed by Drs Frank Smithies, Chicago, Kenneth M Lynch, Charleston, S C, and W M James, Panama, R P

Drs Alexius McGlannan and Standish McCleary, Baltimore, presented a paper on 'Carcinoid Tumors of Small Intestine Report of a Case Complicated by Intussusception in an Adult '

Dr Frank C Yeomans, New York, read a paper on "Carcinomatous Degeneration of Rectal Adenomas Report of Seven Cases"

These two papers were discussed by Drs J P Pratt, Detroit, Joseph C Bloodgood, Baltimore, Curtice Rosser, Dallas, Texas, Alois B Graham, Indianapolis, Alexius McGlannan, Baltimore, and Frank C. Yeomans, New York

Thursday, May 19—Afternoon

Dr Jerome M Lynch, New York, read the chairman's address, entitled "A New Operation for Prolapse of the Rectum"

Dr Alois B Graham, Indianapolis, read a paper on "Anorectal Diseases Present Status of Diagnosis and Treatment" Discussed by Drs Frank C Yeomans, New York, E G Martin, Detroit, John A Lichty, Clifton Springs, N Y , Arthur A Landsman, New York, E H Terrell, Richmond, Va , and Alois B Graham, Indianapolis

Drs Burrill B Crohn and Herman Rosenberg, New York, presented a paper on Nonspecific Ulcerative Colitis" Discussed by Drs Moses Paulson, Baltimore, Anthony Bassler, New York, Arthur A Landsman, New York, F B Turck, New York, and Burrill B Crohn, New York

Dr C L Hartsock, Cleveland, read a paper on "Abdominal Migraine" Discussed by Drs John A Lichty, Clifton Springs, N Y , A F R Andresen, Brooklyn, Zachary Sagal, New York, and C L Hartsock, Cleveland

Dr A C Ivy, Chicago, read a paper on "Further Studies on the Physiology of External Pancreatic Secretion" Discussed by Drs H L Bockus, Philadelphia, Anthony Bassler, New York, Lloyd Arnold, Chicago, and A C Ivy, Chicago

Dr William H Stewart, New York, read a paper on "Cholecystography ' Discussed by Drs Maurice Feldman, Baltimore, Bernard Fantus, Chicago, I O Palefski, New York, George B Eusterman, Rochester, Minn , and William H Stewart, New York

Dr V E S Counseller, Rochester, Minn , read a paper on The Effects of Obstructive Lesions of the Common Duct on the Liver" Discussed by Drs Alexius McGlannan, Baltimore, C S McVicar, Rochester, Minn , and V E S. Counseller, Rochester, Minn

Friday, May 20—Afternoon

The following officers were elected chairman, Dr Joseph Sailer, Philadelphia, vice chairman, Dr Alois B Graham, Indianapolis, secretary, Dr George B Eusterman, Rochester, Minn

Drs Anthony Bassler and J Raymond Lutz, New York, presented a paper on "Deductions from One Hundred Consecutive Testings of Pancreatic Function" Discussed by Drs Harry Shay, Philadelphia, Frank Smithies, Chicago, and Anthony Bassler, New York

Drs C S McVicar and William T Fitts, Rochester, Minn , presented a paper on 'Clinical Aspects of Jaundice" Discussed by Drs A M Snell, Rochester, Minn , and C S. McVicar, Rochester, Minn

Drs H L Bockus and Joseph Bank, Philadelphia, presented a paper on Upper Gastro-Intestinal Diseases Associated with Syphilis" Discussed by Drs George B Eusterman, Rochester, Minn ; Frank Smithies, Chicago, Walter C. Alvarez, Rochester, Minn , and H L Bockus, Philadelphia

Dr Irving Gray, Brooklyn, read a paper on "Duodenal Ulcer Symptom Complex in Patients Not Having Ulcer" Discussed by Drs Julius Friedenwald, Baltimore, A F R Andresen, Brooklyn, C R Jones, Pittsburgh, J J Gilbride, Philadelphia, Frank Smithies, Chicago, and Irving Gray, Brooklyn

Dr Moses Paulson, Baltimore, read a paper on "Experimental Studies on Chronic Ulcerative Colitis with Reference to a Bacterial Etiology" Discussed by Drs F R Brown, Baltimore, Frank Smithies, Chicago, A F R Andresen, Brooklyn, Walter C Alvarez, Rochester, Minn , and Moses Paulson, Baltimore

Drs J P Pratt and L S Fallis, Detroit, presented a paper on Volvulus of Cecum and Ascending Colon Report of Three Cases ' Discussed by Drs V. E. S Counseller, Rochester, Minn , and J. P. Pratt, Detroit

---

SECTION ON RADIOLOGY

Wednesday, May 18—Afternoon

The meeting was called to order at 2 o'clock by the chairman, Dr Albert Soiland, Los Angeles

The name of Dr A Joseph Riviere, Paris, which was presented by President Wendell C Phillips and duly seconded, was placed in nomination for Honorary Fellowship by Dr J T Case, Battle Creek, Mich The nomination was seconded by Dr I S Trostler, Chicago, and by unanimous vote Dr Riviere was elected to Honorary Fellowship

Dr. Albert Soiland, Los Angeles, read the chairman's address, entitled 'Radiology"

Drs H B Thomas, E W Hirsch and Edward S Blaine, Chicago, presented a paper on Unusual Bone Changes Caused by a Small Primary Bronchiogenic Carcinoma" Discussed by Drs A L Gray, Richmond, Va , Leon T Lewald, New York, H K Pancoast, Philadelphia, and Edward S Blaine, Chicago

Drs Irving S Ingber and Frederick H Rodenbaugh, San Francisco, presented a paper on 'Diverticula of the Small Intestine. Incidence and Symptomatology, with Illustrative Case Histories" Discussed by Drs Lewis G Cole, New York, and Frederick H Rodenbaugh, San Francisco

Dr A B Moore, Rochester, Minn , read a paper on "Benign Tumors of the Stomach from the Roentgenologic Point of View" Discussed by Drs George W Holmes, Boston, H K Pancoast, Philadelphia, F B Stephenson, Denver, and A. B Moore, Rochester, Minn

Dr Maximilian J Hubeny, Chicago, read a paper on "Pain. Its Value, Its Elusiveness" No discussion

Drs F E Simpson and R E Flesher, Chicago, presented a paper on "Radium in the Treatment of Vascular Nevi" Discussed by Drs George W Grier, Pittsburgh, W H Schmidt, Philadelphia, and R E Flesher, Chicago

Dr George M MacKee, New York, read a paper on "Summary of Roentgen-Ray Therapy in Dermatology" Discussed by Drs George E Pfahler, Philadelphia, I S Trostler, Chicago, Bertram C Cushway, Chicago, and George M MacKee, New York

Thursday, May 19—Afternoon

Dr Francis Carter Wood, New York, read a paper on "Experimental Investigation of the Therapeutic Value of a

Combination of Colloidal Lead and Roentgen Rays in the Treatment of Cancer." Discussed by Drs. J. Shelton Horsley, Richmond, Va.; Henry J. Ullmann, Santa Barbara, Calif.; Adolph Bonner, Brooklyn, and Francis Carter Wood, New York.

Dr. Henry J. Ullmann, Santa Barbara, Calif, read a paper on "The Combination of Colloidal Lead and Radiation in Cancer Therapy." Discussed by Drs. O. N. Meland, Los Angeles; Francis Carter Wood, New York, and Henry J. Ullmann, Santa Barbara, Calif.

Dr. Douglas Quick, New York, read a paper on "Radium in Massive Dosages in the Therapy of Cancer." Discussed by Drs. Curtis F. Burnam, Baltimore; H. H. Bowing, Rochester, Minn., and Douglas Quick, New York.

Drs. G. E. Pfahler and B. P. Widmann, Philadelphia, presented a paper on "The Value of Injections of Dextrose During Radiation Treatment of Malignant Disease." Discussed by Drs. Howard P. Doub, Detroit; James W. Hunter, Jr., Norfolk, Va.; Truman Abbe, Washington, D. C., and B. P. Widmann, Philadelphia.

Dr. U. V. Portmann, Cleveland, read a paper on "Radiation Therapy in the Treatment of Carcinoma of the Thyroid Gland." Discussed by Drs. Allen Graham, Cleveland; H. H. Bowing, Rochester, Minn., and U. V. Portmann, Cleveland.

Dr. Arthur W. Erskine, Cedar Rapids, Iowa, read a paper on "The Management of Cancer of the Breast." Discussed by Drs. A. W. Crane, Kalamazoo, Mich., and B. H. Orndoff, Chicago.

Friday, May 20—Afternoon

The following officers were elected: chairman, Dr. E. H. Skinner, Kansas City, Mo.; vice chairman, Dr. Charles A. Waters, Baltimore.

It was moved by Dr. P. M. Hickey, Ann Arbor, Mich., seconded and carried, that a committee of three be appointed by the Executive Committee to cooperate with the director of the Scientific Exhibit in connection with radiologic exhibits.

Dr. A. C. Christy, Washington, D. C., presented a resolution that the chairman appoint three members to serve on the committee to study the legislative needs for safeguarding the practice of radiology in the various states, and to report results and recommendations at the next meeting. Motion for adoption was made by Dr. Christy, seconded and carried.

The chairman appointed a committee consisting of Drs. Thomas A. Groover, Washington, D. C.; E. L. Jenkinson, Chicago, and W. E. Chamberlain, San Francisco.

Drs. A. S. Warthin and E. A. Pohle, Ann Arbor, Mich., presented a paper on "The Effect of Roentgen Rays on the Heart." Discussed by Drs. B. H. Orndoff, Chicago; Eugene Kilgore, San Francisco, and E. A. Pohle, Ann Arbor, Mich.

Dr. P. M. Hickey, Ann Arbor, Mich., read a paper on "Standards in Roentgenology." Discussed by Drs. Willis F. Manges, Philadelphia; Henry Kennon Dunham, Cincinnati; C. S. Gorsline, Battle Creek, Mich., and P. M. Hickey, Ann Arbor, Mich.

Dr. F. S. Bissell, Minneapolis, read a paper on "The Metamorphosis of Tuberculous Lung Changes as Observed in Serial Roentgenograms." Discussed by Drs. Willis F. Manges, Philadelphia; Frank B. Stephenson, Denver; Henry Kennon Dunham, Cincinnati, H. K. Pancoast, Philadelphia, and F. S. Bissell, Minneapolis.

Dr. V. V. Norton, Cincinnati, read a paper on "Basal Tuberculous Lesions." Discussed by Drs. H. K. Pancoast, Philadelphia; Henry Kennon Dunham, Cincinnati, and V. V. Norton, Cincinnati.

Drs. Samuel Brown and H. B. Weiss, Cincinnati, presented a paper on "Lateral Views of the Thorax." Discussed by Drs. W. A. Evans, Detroit; H. K. Pancoast, Philadelphia; Henry Kennon Dunham, Cincinnati, and Samuel Brown, Cincinnati.

Dr. William H. Schmidt, Philadelphia, read a paper on "Cancer of the Tongue." Discussed by Drs. Barnet Joseph, New York; James F. Percy, Los Angeles, and William H. Schmidt, Philadelphia.

Dr. Isaac Levin, New York, read a paper on "Intraperitoneal Insertion of Capillary Tubes of Radon in Cancer of the Abdomen and Pelvic Cavities." Discussed by Drs. Barnet Joseph, New York, and Isaac Levin, New York.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALASKA

Hospital News—Airplanes Transport Patients.—Instances have occurred in Alaska in which patients have been transported hundreds of miles by airplanes to hospitals or other medical aid. The Anchorage Base Hospital, maintained by the Alaska Railroad under the U. S. Department of the Interior, with a capacity of thirty-four beds, serves a large territory and admits other patients in addition to the railway employees. Dr. Rex F. Swartz is now chief of staff of the hospital, and the other railroad surgeons at the hospital are Drs. Joseph H. Romig, Fairbanks; John A. Baughman, Seward, and Reilly J. Alcorn, Anchorage. Our correspondent writes also that Dr. Arthur D. Haverstock, captain, Medical Corps, U. S. Army, has been ordered to the Letterman General Hospital, San Francisco; Dr. Haverstock was formerly chief medical officer at the army post at Anchorage.

CALIFORNIA

Health at San Diego.—Telegraphic reports to the U. S. Department of Commerce from sixty-six cities with a total population of about 30 million, for the week ending May 21, indicate that the highest mortality rate (23.1) was for San Diego, and that the rate for the group of cities was 12.4. The mortality rate for San Diego for the corresponding week last year was 18.5, and for the group of cities, 13.3.

Private Kibbe Discharged.—Private Jack A. Kibbe of the Thirtieth Infantry, U. S. Army, one of the soldiers who volunteered to be inoculated with dengue fever in the Philippine Islands, so that medical officers might study the disease, was discharged, June 2, at San Francisco by reason of the expiration of his term of enlistment. He will go to live with his sister at Enfield, Conn., his parents having died during his enlistment. Private Kibbe enlisted from Copper Hill, Tenn. (The Journal, April 18, 1925, p. 1165).

"Spirit Doctor" Treats Virulent Smallpox.—A Mexican "spirit doctor" in Los Angeles County in April treated a case of virulent smallpox, and the patient died. The "doctor" who did not report the case was prosecuted by the county health department; he was also convicted of violating the medical practice act, and was sentenced to serve 180 days in jail. The sentence was suspended for two years. The state board of health bulletin says that a Mexican child who was recently brought into Los Angeles County developed smallpox, and that these cases indicate that virulent smallpox is being brought into the United States from Mexico.

CONNECTICUT

Clinical Congress of State Society.—A preliminary announcement of the Clinical Congress of the Connecticut State Medical Society to be held at Yale University, September 20-22, shows that definite arrangements have been made for seventeen addresses and demonstrations by the following physicians: Drs. James P. Leake, U. S. Public Health Service, Washington, D. C.; Frederick M. Allen, Morristown, N. J.; Francis M. Rackemann, Boston; Fred Wise, New York; Charles G. Heyd, New York; Thomas McCrae, Philadelphia; Leroy M. S. Miner, Boston; John F. Erdmann, New York; John J. Moorhead, New York; Bronson Crothers, Boston; John Whitridge Williams, Baltimore; Ross H. Skillern, Philadelphia; Frank R. Ober, Boston; Prof. Frederick B. Flinn, Ph.D., department of physiology, Columbia University, College of Physicians and Surgeons; Drs. George E. de Schweinitz, Philadelphia; Eugene H. Pool, New York, and Morris Fishbein, Chicago. Yale has assigned one of the college dormitories for the use of the members of the congress and rooms can be had for $2 per night; if hotel rooms are preferred, they may be had at the usual rates. There will be garage and parking space for the use of the members at a convenient location, and twenty-four hour telephone service throughout the congress, an abstract of the papers will be presented to each member in a bound volume. The fee will be $5, including admission to all sessions. Inquiries should be addressed to Dr. Creighton Barker, 129 Whitney Avenue, New Haven.

DISTRICT OF COLUMBIA

Carnival Brings Smallpox to Capital.—The first outbreak of smallpox this year in Washington was reported, May 19; five cases were discovered, all but one occurring in negroes. The health department considered the source of the outbreak to be among members of a carnival company which visited the city. The health department notified the Pennsylvania health authorities of the situation as the show went to that state; word came that one performer was in a hospital in New York with smallpox.

Dinner to Dr. White.—The staff of St. Elizabeth's Hospital gave a dinner in honor of Dr. William A. White, the superintendent, May 13, as an expression of mutual good will and friendliness between the superintendent and staff, and of their confidence in and loyalty to the hospital and its management. St. Elizabeths Hospital has been the subject of various investigations by Congress recently; the dinner was an expression of the relief afforded by the end of the investigations and their favorable results.

FLORIDA

Bills Introduced.—Senate bill 87 would regulate the practice of podiatry, providing for the examination and licensing of podiatrists. Senate bill 614 is an act to provide for sterilization of inmates of state institutions in certain cases. House bill 1056 would provide for the creation of the position of state supervisor of physical and health education.

Personal.—Dr. Joseph N. Fogarty, St. Augustine, has resigned as chief surgeon of the Florida East Coast Railway.——Dr. Harry L. Putnam addressed the Pinellas County Medical Society, St. Petersburg, recently on "Arteriosclerosis," and Dr. Martin H. Stuart, on "Early Treatment of Otitis Media and Mastoiditis."——Dr. John S. P. Turberville, Century, has been elected president of the Florida Railway Surgeons Association.——During the absence in Europe of Dr. Tom A. Williams, Dr. Isadore H. Agos will direct the Child Guidance Clinic at Miami.

IDAHO

Society News.—The Southwest Idaho Medical Association met at Boise, April 1; clinics were held at St. Luke's and St. Alphonsus hospitals, and in the afternoon Dr. Frederick Epplen, Spokane, spoke on "New Views on Nephritis"; Drs. Mitchell Langworthy, Spokane, "Industrial Fractures and Dislocations," and Alphonso N. Codd, Spokane, "Bronchoscopy."

ILLINOIS

Bill Introduced.—House bill 610 establishes a code of standards for schools teaching drugless sciences.

Two Journals Consolidate.—The Chicago *Medical Recorder,* founded forty-nine years ago, and the *Radiological Review,* founded about three years ago, have consolidated, and henceforth will be published by the Radiological Review Publishing Company, 81 East Madison Street, Chicago, under the editorship of Dr. Harold Swanberg, Quincy, and an editorial board of physicians.

State Department Adopts the Kahn Test.—After June 1, 1927, the laboratory of the Illinois Department of Public Health will use the Kahn test as the official serologic test for syphilis in place of the Wassermann test. The Wassermann test will be made on the special request of physicians when conditions seem to warrant additional information. This action was taken on recommendation of the advisory board after a comprehensive study of thousands of tests.

Liquor Licenses Revoked.—The district prohibition administrator, with headquarters in Chicago, recently revoked the liquor licenses of the following for violation of the prohibition law and regulations:

Dr. William H. Finn, Chicago.
Dr. Chester W. Fouser, Cicero.
Dr. James T. Groot, Chicago.
Dr. Robert R. Mustell, Chicago.
Dr. Samuel T. Sealy, Mounds.
Dr. Robert G. Smith, Waukegan.
Dr. Marcus G. Wolk, Calumet City.

State Medical Election.—At the seventy-seventh annual meeting of the state medical society, Moline, May 31-June 2, Dr. G. Henry Mundt, Chicago, became president of the society; John E. Tuite, Rockford, president elect; Drs. Arthur T. Leipold, Moline, and Arthur G. Bosler, Chicago, vice presidents; Dr. Harold M. Camp, Monmouth, secretary, and Dr. A. J. Markley, Belvidere, treasurer. Chicago was selected for the 1928 meeting. The oration in medicine was given by Dr. Elliott P. Joslin, Boston, and the oration in surgery by Dr. Charles H. Mayo, Rochester, Minn. Dr. Robert M. Schauffler, Kansas City, addressed the opening meeting, to which the public was invited, on "Why You Need the Physician When You Are Not Sick." At the president's banquet, thirteen of the nineteen living past presidents were present. Many of the physicians in attendance at this meeting availed themselves of the opportunity to undergo a physical examination which was conducted by Drs. James H. Hutton and Hubbard P. Saunders, Chicago.

IOWA

Students Protest Against Resignations.—About 180 upper classmen of the State University of Iowa College of Medicine, Iowa City, adopted resolutions, May 31, protesting, it is reported, against the acceptance by the state board of education of the resignations of several faculty members.

State Medical Election.—At the recent medical meeting of the Iowa State Medical Society, Council Bluffs, Dr. Michael J. Kenefick, Algona, was installed as president; Dr. Thomas E. McManus, Waterloo, was made president-elect, and Dr. Tom B. Throckmorton, Des Moines, secretary, reelected.

Society News.—Dr. Donald MacRae, Jr., Council Bluffs, was recently elected president of the newly organized Iowa Surgical Clinical Society.——The Iowa Public Health Association has elected Dr. Herbert R. Sugg, Clinton, president; Dr. Reu L. Barnett, Atlantic, vice president, and Dr. Harley L. Sayler, Des Moines, secretary-treasurer.

Veterans' Bureau Needs a Pathologist.—The U. S. Veterans Bureau Hospital at Knoxville needs a pathologist, and applications for the position are being received by the U. S. Civil Service Commission, Washington, D. C. The entrance salary is $3,800, advancement depending on efficiency and the occurrence of vacancies in higher positions; $6,000 is the highest salary paid to senior medical officers. Competitors will not be required to report for examination at any place, but will be rated on their education, training and experience.

MAINE

Personal.—Dr. Henry L. Johnson of Westerly, R. I., was appointed college physician of Bowdoin College at a meeting of the governing board, April 15. Dr. Johnson will succeed the late Dr. Frank N. Whittier.

State Medical Meeting.—The annual meeting of the Maine Medical Association will be held at Portland, June 13-15, under the presidency of Dr. Lester P. Gerrish, Lisbon Falls; there will be a symposium on metabolic diseases by Drs. Frederick M. Allen, New York, Garfield G. Duncan, Philadelphia, and Elton R. Blaisdell, Portland, Ore. Dr. L. Rock Sleyster, Wauwatosa, Wis., a trustee of the American Medical Association, will give the address at the banquet, Tuesday evening; there will be dancing. There will be a cardiac clinic at the Maine General Hospital, Wednesday morning, and among others, Dr. Daniel F. Jones, Boston, will read a paper on "Carcinoma of the Rectum." Dr. Conrad Berens, Jr., New York, will address the eye and ear section, June 25, in Portland.

MASSACHUSETTS

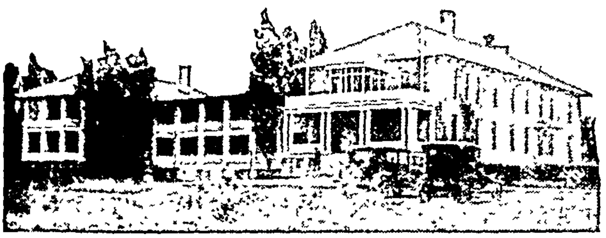
Medical Student Sentenced.—On complaint of the department of public safety, John C. Del Toro, a student in the College of Physicians and Surgeons, Boston, was brought into court recently where, it is reported, testimony indicated that he had been practicing medicine without a license. Del Toro is said to have been sentenced to three months in jail.

Another Physicians' Art Exhibit.—Arrangements are being made for an exhibition of works of art by physicians of New England. The exhibition is expected to open about November 1 at the Boston Medical Library. A number of physicians have already indicated their desire to participate. Any member of the profession in New England who is willing to loan works of art made by himself for the exhibition is invited to do so. Further particulars can be had on request to the Boston Medical Library, 8 The Fenway, Boston, Mass., in care of Dr. George H. Monks, for the committee.

Society News.—At the annual meeting of the Essex South District Medical Society, Gloucester, May 10, Dr. Edward B. Hallet, Gloucester, was elected president; Mr. Arthur W. Gilbert, Belmont, addressed this meeting on "Experiences in Europe with the League of Nations," illustrated. Mr. Gilbert was one of the three Americans appointed by the President to attend the conference on the League of Nations.——Dr. Philemon E. Truesdale was elected president of the Bristol South District Medical Society, May 5.——Dr. Frank H. Washburn, Holden, was elected president of the Worcester District Medical Society at the annual meeting, May 11; Dr. Albert M. Shattuck gave an address following the banquet on "Fifty Years," in which he reviewed the progress of medicine.

Loan Fund for Harvard Students.—The *Boston Medical and Surgical Journal* notes that the Medical School of Harvard University, beginning with those entering in 1927, has increased its tuition to $400 a year, and coincidentally will provide a loan fund from which students who enter in that year or thereafter may borrow. Loans will be made to students in the second, third and fourth year classes, and occasionally to men in the second half of the first year, but in all cases to those whose records have been sufficiently creditable to make it probable that they will remain in the school. Beginning this year, all applicants for admission to the school living within 50 miles of Boston will be required to have a personal interview with the assistant dean or a member of the committee on admission.

State Opens Cancer Hospital.—Governor Fuller will preside at the exercises, June 21, which will formally open the Pondville Hospital at Norfolk, an institution provided by the state in an effort to control cancer. Eight buildings erected in 1912 as a branch of the Foxboro State Hospital for Mental Diseases have been refitted; two of the larger buildings are represented in the picture. The institution is in a grove of evergreens, birches and poplars on the main highway to Providence, 30 miles south of Boston. It has ninety-five beds to be used for all types of cancer, modern surgical equipment, roentgen-ray apparatus, radium and a resident radiologist. There is an adequate visiting and consulting staff. Dr. Lyman A. Jones will be the superintendent.



MINNESOTA

New Fellows at Mayo Foundation.—The following physicians, recently appointed fellows at the Mayo Foundation, are majoring in the subjects indicated:

Dr. Charles Grant Bain, Tofield, Alberta, surgery.
Dr. Harry Hamilton Cooke, Minneapolis, surgery.
Dr. Finis G. Cooper, Huntington Park, Calif., surgery.
Dr. David C. Ditmore, Buffalo, Ill., surgery.
Dr. Wilmot C. Foster, Portland, Ore., surgery.
Dr. Clarence Oliver Heimdal, Deerfield, Wis., surgery.
Dr. Wilbur W. Holland, Aberdeen, Md., surgery.
Dr. George E. Malmgren, St. Paul, surgery.
Dr. James M. Marshall, Tooele, Utah, surgery.
Dr. Hamline Mattson, Minneapolis, surgery.
Dr. David Metheny, Philadelphia, surgery.
Dr. Harry T. R. Mount, Springfield, Ontario, surgery.
Dr. Edward H. Ray, Auburn, Ala., surgery.
Dr. Lloyd T. Sussex, Hope, N. D., surgery.
Dr. Fred R. Thompson, Chicago, surgery.
Dr. William A. Bunten, Worland, Wyo., neurologic surgery.
Dr. William A. S. Magrath, Wynyard, Saskatchewan, ophthalmology.
Dr. James S. White, Covington, Ga., ophthalmology.
Dr. Harry A. Daniels, Eveleth, Minn., medicine.
Dr. David G. Ghrist, Hollywood, Calif., medicine.
Dr. Harry M. Margolis, Pittsburgh, medicine.
Dr. Wallace T. Partch, Greenacres, Wash., medicine.
Dr. Roland E. Nutting, Minneapolis, pediatrics.
Dr. Curtis T. Prout, Portchester, N. Y., neurology.
Dr. Dale L. Martin, Orland, Calif., pathology.
Dr. William B. Norment, Trinity, N. C., surgery.
Dr. Carlos Gustavino, Valencia, Spain, surgical pathology.
Dr. Frances Johnson, Red Wing, Minn., biophysics.

Society News.—The Minnesota Society of Internal Medicine offers a cash prize of $250 for the best thesis by any practicing physician, exclusive of members of the society, in Minnesota who has been deemed most worthy to receive a prize in research and clinical medicine; the thesis must be received before Jan. 1, 1928; the secretary is Dr. Edwin L. Gardner, 610 Yeates Building, Minneapolis.——Dr. Arthur C. Strachauer, Minneapolis, addressed the Ramsey County Medical Society, April 25, on "Carcinoma of the Large Bowel."——The West Central Minnesota Medical Society will hold an outing at Ortonville, June 19.——The Southwestern Minnesota Medical Society voted to spend about $250 for a university extension course, the first meeting of which was held at Windom, May 9; Dr. William A. O'Brien of the University of Minnesota addressed the society, April 28, on "Diseases of the Thyroid Gland."——Dr. George E. Sherwood, Kimball, was elected president of the Stearns-Benton County Medical Society at the meeting, April 27.——Among others, Dr. Winford P. Larson of the University of Minnesota Medical School addressed the Chisago-Pine County Medical Society, April 26, on "Development of Scarlet Fever Vaccine"; Dr. Carl W. Paulson, North Branch, was elected president at this meeting——Dr. Stanley R. Maxeiner, Minneapolis, addressed the Redwood-Brown County Medical Society, May 3, on "Surgery of Tuberculous Patients," and Dr. Henry P. Wagener, Rochester, on "Effect of Various Diseases on the Fundus"; Dr. Abraham Franklin Strickler, Sleepy Eye, was elected president at this meeting.

MISSISSIPPI

***State Medical Election.**—At the annual meeting of the* Mississippi State Medical Association, Vicksburg, Dr. John Darrington, Yazoo City, was elected president, and Dr. Thomas M. Dye, Clarksdale, reelected secretary. The next meeting will be held at Meridian, May 8-10, 1928.

NEBRASKA

State Medical Election.—At the annual meeting of the Nebraska State Medical Association, held, May 10-12, at Lincoln, Dr. Benjamin R. McGrath, Grand Island, was elected president, and Dr. Roy B. Adams, Lincoln, reelected secretary. The next meeting will be held at Hastings, in May, 1928. The new president takes office, Jan. 1, 1928.

Tuberculosis Association Meeting.—At the annual meeting of the Nebraska Tuberculosis Association, in Omaha, April 8, the officers were reelected as follows: Drs. Solon R. Towne and Williams N. Anderson, both of Omaha, president and vice president, respectively, and Dr. Augustus D. Cloyd, Omaha, secretary. The chamber of commerce of Omaha gave a luncheon in honor of Philip P. Jacobs, Ph.D., of the National Tuberculosis Association, which was presided over by Dr. Anderson. Dr. Jacobs' address was on "The Money Value of Human Life." The association's work is financed by the annual Christmas seal sale; with about $22,300 annually, it maintains tuberculosis nurses in dispensaries at Lincoln and Omaha, brings speakers to the state, makes tuberculosis surveys, holds exhibits, distributes tuberculosis literature and sends delegates to the national meeting.

NEW YORK

Liquor Licenses Revoked.—The district prohibition administrator recently revoked the liquor licenses of the following for the reason indicated:

Dr. James A. Campbell, New York City, unlawfully issued prescriptions Form 1403. Illegal possession.
Dr. Louis Greenstein, Brooklyn, issued prescriptions for beverage purposes to fictitious persons.

The Grange Confers with County Medical Society.—Following the death of a boy whose mother was unable to obtain a physician during the night, the Grange of Genesee County appointed a committee to confer with the Genesee County Medical Society with the object of making provisions whereby the rural inhabitants might obtain the services of physicians in emergencies.

Dr. Baldwin Awarded Trudeau Medal.—Dr. Edward R. Baldwin, Saranac Lake, director of the Trudeau School of Tuberculosis, was awarded the Trudeau Medal at the twenty-third annual convention of the National Tuberculosis Association, Indianapolis, May 23, for performing work of world-wide significance in the antituberculosis campaign. The medal was presented by Dr. Theobald Smith, Princeton, N. J., the only other person to whom the Trudeau Medal has been awarded.

Radiologists Award Medal. — At the recent medical congress, Washington, D. C., the American College of Radiology awarded its gold medal to William D. Coolidge, Ph.D., assistant director, research laboratory, General Electric Company, Schenectady, "in recognition of his contribution to radiology and the science of medicine." Dr. Coolidge, who invented the Coolidge tube, has done much in the development of the roentgen ray. On the same day, Dr. Coolidge was awarded the gold medal of the Franklin Institute.

Syracuse Alumni Association.—The Medical Alumni Association held one of its largest reunions, June 10; more than 400 of the alumni were expected to be present. Members of the faculty held a clinical pathologic conference at the medical college in the morning presenting cases from both points of view; Dr Henry W Stiles conducted anatomic demonstrations, and at noon the out-of-town members were guests of the city alumni. The departments of physiology, bacteriology, pathology and pharmacology gave four twenty-minute demonstrations in the afternoon, and Dr George D Stewart, New York, addressed the annual meeting of the University Club at 4 o'clock. The annual banquet was in the evening at the Syracuse Hotel, and the guests were Chancellor Flint and Dr Stewart. Following this there was a program of entertainment.

New York City

Appointments and Promotions at New York University.—An announcement was made, May 26, of appointments and promotions at New York University, among which was that of James Kendall, Sc D, as head of the graduate school. Dr. Isaac Levin was appointed clinical professor of cancer research in the medical school, and Dr Walter J Highman, clinical professor of dermatology and syphilology. Dr George A. Koenig was promoted to clinical professor of surgery; Dr. Clement J Halpern to clinical professor of dermatology and syphilology, and Gustave J. Noback, Ph D, to associate professor of anatomy.

Personal.—F. Stanley Howe, assistant business manager of the Rockefeller Institute for Medical Research for about seven years, has resigned to become director of the Orange Memorial Hospital, Orange, N J.——Dr. Walter F Dannreuther has been appointed director of the department of gynecology at the New York Post Graduate Medical School.——Dr Louis Albert Thung has been chosen president of the medical staff of the Swedish Hospital, New York.——Dr George E Brewer, according to the New York *Medical Week*, has announced his intention to retire after this year. He plans to take up anthropology as his field of activity.

Forging Names on Narcotic Prescriptions.—During 1926, eight persons in the New York district were arrested by the federal narcotic unit for forging physicians' names on prescriptions for narcotics, during April, 1927, five women were arrested, one a student, in the act of forging the names of physicians on blanks which had been improperly secured. Unless such prescriptions are for unusual amounts, the forgery usually escapes the notice of the pharmacist. The department of health and the federal authorities would appreciate the effort of physicians and institutions using narcotic forms in prescription style to do everything possible to prevent their falling into the hands of persons who may use such forms illegally to secure drugs.

Hospital News.—The police commissioner has abolished four of the five police clinics in the various boroughs, retaining only the one at the Manhattan headquarters; disabled policemen will go now to the offices of the police surgeons.——Dr Isidore H Goldberger gave three postgraduate lectures at the Willard Parker Hospital, April 26-28, on "Modern Management of Diphtheria, Measles and Scarlet Fever."——Dr Otto Glogau has been appointed otolaryngologist to the Community Hospital, New York.——The Italian Hospital is conducting a drive for $2,000,000 to erect a new building and a training school for nurses.——Maple trees were planted on Memorial Day at the U. S. Veterans' Hospital, West Kingsbridge Road, in memory of four physicians who have died while on the medical staff; namely, Drs. Alfred P. Chronquest, John J. Hughes, Marcus B. Heyman and Isham G. Harris.

Inventory of Social Assets.—The Welfare Council of New York announces plans for a study and inventory of the social assets and liabilities of New York City. The Laura Spelman Rockefeller Foundation and the Commonwealth Fund have made grants amounting to $300,000 for the next five years for this work, provided the council raises the funds required for its general administrative budget. A research bureau has been created by the council to carry on the study and Neva R. Deardorff of the Children's Commission of Pennsylvania has been appointed director. The research bureau will undertake immediately, in cooperation with the social agencies of the city, (1) a study of the income and expenditures of New York City social agencies, (2) an inventory of the public health resources of the community other than those operated by the department of health; (3) a study of the settlement house situation to discover what is being done in this field by 115 institutions. The welfare council has been requested to take up several other projects, one of which is the study of the situation created by the removal of the clinics and hospitals from the west side to the new medical center in Washington Heights. Decisions on this and other projects are still pending. Robert E Chaddock, Ph D, professor of statistics, Columbia University, has been appointed consultant to the research bureau. The council will have the assistance also of an advisory research committee of about sixteen members, among whom are Dr. Louis I. Harris, commissioner of health, and Dr Haven Emerson, Columbia University College of Physicians and Surgeons. There is an outstanding need for this study in New York, Robert deForest, president of the council, says, because of the diversity of the social problems present and the vast amount of money needed for charitable and welfare enterprises each year. Mr. de Forest considers this amount exceeds $100,000,000.

OHIO

Resolution About Medical Ethics.—The house of delegates of the Ohio State Medical Association, at the recent Columbus meeting, adopted a resolution recommending to the medical colleges of the state of Ohio that provision be made in the medical curriculum for definite medical courses on the social relations of the physician, including medical ethics, economics, jurisprudence and medical history.

State Medical Golf Champion.—Dr. Wesley L. Furste, Cincinnati, won the championship of the Ohio State Medical Golfing Association at the seventh annual tournament, held during the state medical meeting at Columbus, and was elected president of the golfing association. Dr. Furste's low gross score for thirty-six holes was 169. One hundred and forty-seven members entered the lists to compete for various honors in the tournament.

Personal.—Dr. Emery R. Hayhurst, professor of hygiene, Ohio State University College of Medicine, Columbus, has been elected vice president of the Ohio Academy of Science.——Dr. Samuel B. McGuire has been reelected president of the staff of Union Hospital at Dover.——Dr. Dudley W. Palmer was elected president of the Cincinnati Academy of Medicine, May 23; Dr. Joseph Brennemann, Chicago, addressed this meeting on "Common Sense in Infant Feeding."

County Society News.—Dr. George S. Derby, professor of ophthalmology, Medical School of Harvard University, Boston, addressed the Academy of Medicine of Cincinnati, April 18, on "Methods of Combating Glaucoma." The academy held its third annual dinner at the Hotel Alms, May 2; the guest of honor was Mayor Seasongood.——Dr. James M. Phillips, Columbus, addressed the Warren County Medical Society, Lebanon, on "Rabies."——The Green County Medical Society will celebrate its seventy-third anniversary in June.——Dr. Irving W. Potter, Buffalo, addressed the Academy of Medicine of Lima and Allen County, Lima, April 19, on "Version," and conducted a clinic at St. Rita's Hospital.——Drs Frank J. Gallagher and Edgar P. McNamee, both of Cleveland, addressed the Hancock County Medical Society, Findlay, April 8, on "Lung Abscess" and "Value of Cholecystography in Diagnosis of Gallbladder Disease," respectively.——Dr. Milton B. Cohen, Cleveland, addressed the Trumbull County Medical Society, Warren, April 21, on "Causes of Failure in Treatment of Hay-Fever and Asthma."——Dr. Allen Graham, Cleveland, addressed the Summit County Medical Society, May 3, on "Toxic Goiter."——Dr. Irwin H. Cutler, Louisville, Ky, addressed the Hempstead Academy of Medicine, Portsmouth, May 9, on "Pyelonephritis."——Dr. C Jeff Miller, New Orleans, gave the fourth annual Gilliam Memorial Lecture before the Columbus Academy of Medicine, April 18, on "Modern Conception and Treatment of Uterine Fibroids."

OKLAHOMA

State Medical Election.—At the annual meeting of the Oklahoma State Medical Association, Muskogee, May 5, Dr Joseph S. Fulton, Atoka, became president; Dr. Ellis Lamb, Clinton, president-elect; Drs. William T. Tilly, Muskogee, Claude T. Hendershot, Tulsa, and Eugene O. Barker, Guthrie, vice presidents, and Dr. Claude A. Thompson, secretary-treasurer and editor. The next meeting will be in Tulsa.

State Policy on Industrial Medicine.—The Oklahoma State Medical Association passed a resolution at its recent annual meeting concerning an ethical tendency in the employment of physicians for injured workmen. Realizing the right of the workman to employ a physician of his choice, the society resolved to consider it unethical for any member to display in any industrial establishment a placard indicating that he has the exclusive right to attend injured workmen therein. It was further resolved that the association appoint a committee of five to meet with representatives of the labor unions, the industrial commission and insurance companies with a view to bringing the industrial practice in the state into conformity with the ethics of the association.

PENNSYLVANIA

Personal.—Dr. Howard C. Frontz, Huntingdon, formerly president of the state medical association, has been elected president of the Pennsylvania Public Health Association to succeed the late Dr. Carey J. Vaux.——Dr. Emlyn Jones, Johnstown, has been appointed chief of the bureau of vital statistics of the state health department, succeeding Russell B. Tewksbury, D.Sc.

Conference on Industrial Nursing.—The state secretary of labor and industry has called a conference on industrial nursing for June 14 at Harrisburg in cooperation with the state department of health, to bring together employers, employees and members of professions to discuss the possibilities of medical care for industrial workers from a practical and technical point of view. About 100 employers have indicated that their industrial nurses will be present. The speakers will include, among others, Dr. Wade Wright, assistant medical director, Metropolitan Life Insurance Company, New York; Dr. Loyal A. Shoudy, chief surgeon, Bethlehem Steel Corporation, and Dr. Lewis R. Thompson, U. S. Public Health Service. The general discussion on industrial nurses and safety will be led by Dr. Edwin H. McIlvain, Philadelphia, and the discussion on industrial nurses and health by Dr. William J. McConnell. There will be a special luncheon meeting for the nurses in attendance.

Philadelphia

Personal.—Dr. and Mrs. Louis von Cotzhausen celebrated their golden wedding anniversary, February 10.——Dr. Wilmer Krusen, director of public health, was guest of honor at a reception at the Hotel Bellevue-Stratford, May 27, given by the Philadelphia College of Pharmacy and Science, of which Dr. Krusen was recently made president.

Society News.—The June 8 meeting of the Philadelphia County Medical Society was "branch night"; each of the six branches provided a speaker. The society has now an honor room in its new building, and has placed therein a memorial tablet on which are the names of eight of its members who died during the World War. Other tablets will be placed there from time to time, reciting the services of members whom the society desires to memorialize.

Jefferson's Drive for Funds.—A drive for $1,500,000 for a new building at Jefferson Medical College will be conducted, June 6-14. The present building, erected in 1898, is inadequate, and will be remodeled for an outpatient department when the new building is completed. Jefferson Medical College and Hospital then will comprise a group of nine buildings. The drive is under the direction of Dr. William W. Keen and Mr. James W. Willcox, one of the trustees. Every member of every team assisting in the drive has been given a copy of Mr. Willcox' cogent "reason why" every "prospect" should become a contributor. It is a small folder in which the question "In what way does the medical college concern me?" is answered. The Journal hopes to be able to present soon a drawing of the new building.

Changes in Faculty at Jefferson.—Dr. Solomon Solis Cohen, for forty-three years a teacher in various capacities at Jefferson Medical College of Philadelphia, has resigned the chair of professor of clinical medicine on account of his age; Dr. Cohen will continue to practice medicine. The departments of medicine and clinical medicine at Jefferson Medical College have been consolidated, Dr. Thomas McCrae remaining head of the department. Dr. Ross V. Patterson, the dean, will take over the clinical work formerly conducted by Dr. Cohen, who has been elected emeritus professor. Dr. Frederick J. Kalteyer has been elected a professor of medicine, and Drs. Edward J. G. Beardsley and Elmer H. Funk, professors of clinical medicine. Dr. Jacob Earle Thomas, recently associate professor of physiology at St. Louis University School of Medicine, St. Louis, has been elected professor of physiology at Jefferson.

SOUTH DAKOTA

State Medical Election.—At the annual meeting of the South Dakota Medical Association, held, May 3-5, at Huron, Dr. Silas M. Hohf, Yankton, was elected president, and Dr. John F. D. Cook, Langford, reelected secretary. The next meeting will be held at Hot Springs, in May, 1928.

UTAH

State Medical Meeting and Postgraduate Course.—The postgraduate instruction offered by the Utah State Medical Association will precede the annual meeting this year being held June 20-22, and will feature diseases of the bone and gynecologic conditions. Dr. Emmet Rixford, professor of surgery, Stanford University School of Medicine, will devote most of three days to lecturing on fractures, and Dr. Palmer Findley, Omaha, will give about the same time to instruction in gynecology. A laboratory course will be given at the University of Utah School of Medicine throughout the week. The registration fee is $10. At the annual medical meeting, June 23-25, Drs. Harold L. Amoss, and Dean Lewis, both of Johns Hopkins University Medical Department, Baltimore; Dr. Frank Hinman of the University of California Medical School, and Dr. Robert B. Osgood of the Medical School of Harvard University, Boston, and other nationally known speakers will appear on the program.

WASHINGTON

First Meeting of Society in Spokane in Ten Years.—The annual meeting of the Pacific Coast Oto-Ophthalmological Society, Spokane, June 6-11, according to the Spokane *Chronicle*, was the first meeting of the society in that city since 1917. Dr. Carroll L. Smith, Spokane, presided; among the guest speakers were Drs. Walter B. Lancaster, Allen Greenwood and Harris P. Mosher, all of Boston; James M. Patton, Omaha; Ross H. Skillern, Philadelphia; Robert C. Lynch, New Orleans; Burt R. Shurly, Detroit; Hanau W. Loeb, St. Louis; Joseph C. Beck, Chicago; Thomas E. Carmody, Denver; Frank R. Spencer, Boulder, Colo.; Thomas H. Halstead, Syracuse, N. Y., and William P. Wherry, Omaha. During the meeting, representatives of the American Board of Ophthalmology and the American Board of Oto-Laryngology conducted examinations for membership in the national societies.

WEST VIRGINIA

Action on Bills.—The West Virginia State Medical Association sponsored the bill recently passed by the legislature to establish a tuberculosis sanatorium in the southern part of the state; the $216,000 earned by state hospital number 1 at Welch will be applied toward its construction. The state association also cooperated in defeating the bills providing for the healing of the sick by spiritual means and for limiting the working hours of nurses to eight a day.

Picturesque Setting for State Medical Meeting.—Members of the West Virginia State Medical Association will gather among beautiful surroundings at the Greenbrier Hotel in White Sulphur Springs for the annual meeting, June 21-23. Furthermore, it is urged that the wives of members see that their husbands attend the convention and accompany them. The Midland Trail from Huntington to White Sulphur Springs has never been better, the road from Parkersburg to Charleston was completed last year, and the Shenandoah Valley Route is recognized as one of the most beautiful drives in the east. A golf tournament will be played, Monday; Dr. Chester R. Ogden, Clarksburg, the president, will preside at the opening session, Tuesday, and Dr. Jabez N. Jackson, Kansas City, President of the American Medical Association, will speak; among other speakers at the scientific sessions will be Drs. John Shelton Horsley and Claude C. Coleman, Richmond, Va.; Gabriel Tucker and Joseph Sailer, Philadelphia; John E. Monger, Columbus, Ohio; William A. Frontz, Robert Tunstall Taylor and Waitman F. Zinn, Baltimore; George W. Crile, Cleveland; Andrew C. Ivy, Chicago, and J. Sydney Ritter, New York. The oration in medicine will be delivered by Dr. Charles P. Emerson, Indianapolis.

WISCONSIN

Bills Introduced.—House bill 654 would establish a county home for the feebleminded in counties having population of 250,000 or more. House bill 696 and T. N. 700 would prohibit the sale or possession of cosmetics containing lead, mercury or other poisonous substances.

GENERAL

Medical Courses in English at Paris.—The Medical Faculty of Paris has organized a course of lectures and demonstrations to be given in English, in October, for 50 francs a lesson per person They will cover diseases of the lungs, nerves and heart, diseases of children, obstetrics and gynecology, diseases of bones and joints, ophthalmology and other specialties, among the instructors will be some of the most prominent physicians in Paris A detailed program of each course can be obtained by writing to the secretary of the A D R M, Salle Béclard, Faculte de médecine, 12, rue de l'Ecole de medecine Paris, VI

College Credit for Sight Saving Study.—The National Committee for the Prevention of Blindness announces that university credits will be given for work done in pursuit of courses in sight saving classes at the University of Southern California, Los Angeles, the University of Cincinnati, Cincinnati, and Peabody College, Nashville, Tenn. There are now 265 sight saving classes in the United States, and according to the director of the National Committee for the Prevention of Blindness, there should be about 5,000 to provide a normal education for the children who have seriously defective vision The experience of the classes already in existence shows, it is said, that it is possible to educate in the public schools many children with seriously defective vision who, though not blind, in former years found their only opportunity for education in schools for the blind Inquiries may be addressed to the National Committee for the Prevention of Blindness, 370 Seventh Avenue, New York

Society News—At the twelfth annual meeting of the American Association of Industrial Physicians and Surgeons, May 16 17 Baltimore, Dr Thomas R. Crowder, Chicago, was elected president, Drs Clare F. N. Schram, Beloit, Wis, and Robert S Quimby Watertown, Mass, vice presidents, and Dr Frank L Rector, Chicago, secretary-treasurer——Elmer V McCollum Ph D, Baltimore, was elected president of the American Society of Biological Chemistry, and D. Wright Wilson, Ph D, Philadelphia, secretary at the annual meeting in Atlantic City N J, April 14-16 The next annual meeting will be held at Ann Arbor, Mich——Dr. Louis A. Buie, Rochester Minn, was elected president of the American Proctologic Society, and Dr Walter A. Fansler, Minneapolis, secretary at the annual meeting in Philadelphia, May 12-14.——Dr John Claxton Gittings Philadelphia, was elected president of the American Pediatric Society, and Dr Howard C Carpenter Philadelphia, secretary, at the annual meeting, May 12 15 The next meeting will be held, April 30-May 2, 1928, at Washington D C——Dr. Henry G Bugbee, New York, was elected president of the American Association of Genito-Urinary Surgeons, Dr William C Quinby Boston, vice president and Dr Herman L Kretschmer, Chicago, secretary at the annual meeting in Absecon, N J, May 9-11 The next meeting will be held in Washington, D. C, in 1928.——Dr Evarts A Graham, St Louis, was elected president of the American Association for Thoracic Surgery, and Dr Ethan Flagg Butler, reelected secretary, at the annual meeting in New York, May 9-11 The next meeting will be held at Washington, D C, May 1-2, 1928——Dr Emmet Rixford, San Francisco, was elected president of the American Surgical Association, and Dr Lincoln Davis, Boston, secretary, at the annual meeting in Richmond, Va, May 12-14 The next meeting will be held at Washington, D C, May, 1928——Dr Elizabeth B Thelberg, of the faculty of Vassar College, Poughkeepsie, N Y, is president of the Medical Women's National Association, and Dr Louise Tayler Jones, Washington, D C, is president-elect——At a meeting of the medical and surgical section of the American Railway Association, May 17, at Richmond, Va, the officers were reelected as follows Dr William H. Bohart, Chicago, chairman, Drs Leonard A. Ensminger, Indianapolis, and Samuel C Plummer, Chicago, vice chairmen, and J C Caviston, New York City, secretary——The New England Society of Physical Therapeutics met, May 25, at the Ring Sanatorium and Hospital, Arlington Heights, Mass, under the presidency of Dr. Elmer F Otis, Melrose Dr Philip H Greeley, Portsmouth, N H. and Dr. Arthur H. Ring, Boston, read papers, about fifty physicians from the New England states were present——Dr Henry Longstreet Taylor, St Paul, Minn, was elected president of the National Tuberculosis Association at the annual meeting in Indianapolis, May 23-26, Drs William C White, Washington, D C, and Alfred Henry, Indianapolis, vice presidents; Dr Charles J Hatfield, Philadelphia, secretary and Henry B. Platt, New York, treasurer——Carl Voegtlin, Ph D, Washington, D C, was elected president of the Federation of American Societies for Experimental Biology, and Dr. Edgar D. Brown, Minneapolis, secretary. The next meeting will be held in the spring of 1928 at Ann Arbor, Mich.

LATIN AMERICA

Personal.—Dr. Harlin A. Harris, formerly of Mazatlan, Mexico, has been appointed chief surgeon of the Southern Pacific Railroad Company of Mexico to succeed Dr. Emile C House, Empalme, Sonora.——Prof Abreu Fialho was appointed dean of the School of Medicine of Rio de Janeiro by the president of Brazil, February 4.

Commencement at School of Tropical Medicine.—The School of Tropical Medicine of the University of Porto Rico, under the auspices of Columbia University, New York, held its commencement exercises, May 11, in the assembly hall at San Juan, P R There were twenty-nine students in this the first year of the school, of whom one, Dr. Gurbox Singh Sant of Amritsar, India, received a "Certificate in Tropical Medicine" The speakers at the exercises included, among others, Dr Robert A Lambert; Thomas E. Benner, chancellor of the University of Porto Rico, and Dr. James W. Jobling, of Columbia University College of Physicians and Surgeons. Drs Gutierrez Ortiz and Goyco represented the medical profession of Porto Rico, and the Rev. Gonzalez Palacios, Valencia, Spain, represented the student body.

FOREIGN

New Site for London University.—The University of London has acquired a new eleven acre site just north of the British Museum in Bloomsbury. Part of the funds necessary to make the purchase were provided by the Rockefeller Foundation This is a central location; the present university buildings are said to be scattered about the city. The British government bought this site several years ago for the university, but the university was unable to accept the government's offer on account of certain conditions attached.

International Congress of Psychology.—Dr. Alfred Adler, Vienna, will give the introductory lecture at the fourth International Congress for Individual Psychology, which will take place in that city, September 17-19. The first session will be devoted to the subject of "The Prevention and Treatment of the Psychoses" Sunday will be devoted to the prevention and treatment of problem children and criminals, and Monday to lectures by prominent scientists of Vienna. The lectures will be in English, French or German. Application for membership and other details should be addressed to Dr. Carl Novotny, Untere Weisgerberstrasse 16/17, Vienna, 111/2, Austria.

Brussels Medical Convention.—The seventh session of the Brussels Medical Convention, organized by the Bruxelles-Médical, will be held, June 25-29; Prof Jean Verhoogen of the Academie royale de médecine will serve as chairman Prof. Pierre Mauriac of Bordeaux will speak at the opening session on "The Confines of Medicine" The program will deal with the theoretical and practical aspects of many important problems of medicine. Among the speakers will be MM. Besredka, Pasteur Institute, Paris; Viggo Christiansen, Copenhagen; Gomez Ulla, Madrid, and Maurice Chiray, Paris The Association générale des dentistes de Belgique will participate. The registration fee will be 75 francs ($3). Dr. R. Beckers, 62 Rue Froissart, à Bruxelles, Belgium, is the secrétaire-général.

Deaths in Other Countries

The report of the death of **René Schickelé**, of the University of Strasbourg, in The Journal, May 28, was erroneous: it was **Gustave Schickelé** and not **René** who died.——**Edmond Rouffart**, professor of gynecology, University of Brussels, founder of the Belgian Society of Gynecology and Obstetrics, May 20, at Brussels, aged 72——**W. Filehne**, formerly professor of pharmacology, aged 83——**Franziska Tiburtius**, said to be the first woman physician in Germany, aged 84

CORRECTION

Efficiency of Female Mammary Gland.—In The Journal, June 4, page 1853, appeared an abstract of an article by A Kollmann, entitled "Functional Efficiency of the Female Mammary Gland." The original article appeared in the *Archiv fur Kinderheilkunde*, Stuttgart, of Jan. 26, 1927 Because of the use, frequent in German, of the comma in place of the decimal point, the quantity was given as 1,611,980 liters instead of 1,611 980 liters

The World List of Scientific Bibliography

The World List of Scientific Periodicals published by the Oxford University Press has been completed. Few as large, and certainly no more arduous, tasks in bibliography have ever been accomplished. The first part of this great undertaking was to compile in alphabetical order a list of all periodicals containing the results of scientific research in existence between the years 1900 and 1921. This was published as volume 1 in 1925. It contains the stupendous number of just over 24,000 separate periodicals. But the list was not complete, notwithstanding the exhaustive search of known catalogues made by Dr. Pollard, then keeper of printed books at the British Museum, and in a supplement issued with volume 2, more than 600 periodicals have been added. The preparation of the second volume necessitated even greater labor and has performed an even more important service to science. The adage "verify your references" is made difficult, sometimes impossible by the ambiguous abbreviations of titles often given by authors. To overcome these difficulties, several institutions have adopted their own sets of abbreviations. These, however are for the most part based on a limited series of periodicals, and also differ among themselves. The second volume of the World List consists in the first place of a set of abbreviations consistent and unambiguous for the whole set of nearly 25,000 periodicals. If it could be universally adopted, the temporary inconvenience of changing existing systems would soon be overcome by the permanent advantage to all scientific workers. Even when a reference is given correctly, the seeker after knowledge has to discover where he can find the periodical. To aid in that, twenty-one centers in Great Britain and Ireland have been selected. Symbols have been assigned to the more important libraries in each of these centers, and after the contraction for each periodical is placed the symbol of libraries in which the periodical is to be found. But apart from the direct aid supplied in this way, some remarkable and disconcerting results have appeared, because for a considerable proportion of the periodicals no home in Great Britain and Ireland has been discovered. Even London, with twenty-seven important scientific libraries, misses many periodicals, some of high value.

The Bleaching of Flour

A committee of eminent physicians and scientists was appointed by the government to consider "whether the practice of treating flour with chemical substances is objectionable on grounds of health, and whether the practice should be prohibited or restricted, and in the latter case what restrictions should be imposed." It has now presented its final report. For flour used for bread making the capacity to make a large, well risen loaf of good texture which shall be white is desired by bakers. Flours deficient in these characteristics are frequently treated with chemical agents, which may be either bleaching agents or 'improvers' or both. The principal bleaching agents are nitrogen peroxide, benzoyl peroxide, chlorine, and nitrogen trichloride. Bleaching was introduced into this country about twenty-two years ago to meet a demand for white bread. Flour, after milling, changes slightly on keeping, its baking qualities improve, and its coloring matter is bleached. This natural aging is probably an oxidation process. Imported flour from America and Australia is kept sufficiently long to exhibit this aging effect. British flours cannot easily be kept because of absence of storage facilities and because of expense. Hence the practice of bleaching enables millers to compete with importers of flour which has the natural advantage of aging.

Bleaching eliminates the difference in appearance between the higher and the lower grades of flour from the same wheat. The higher grades, which are obtained from the hardest part of the endosperm called the semolina, are not only harder but produce a lighter colored flour; these are known as "white" or 'patents" and total about 50 per cent of the flour milled; the remainder are known as 'households." From the latter and softer flour the offal is less perfectly separated. By the use of bleaching a proportion of the 'households' can be made to simulate patents, and a "longer range of patents" can thereby be obtained. Chlorine bleaches by combining with the coloring matter of the flour (carotin), but it also combines with other constituents of the flour. It can act on the tyrosine and tryptophan groupings of the gluten complex with injurious results. The vitamins in flour are very susceptible to traces of chlorine and may be destroyed. Nitrogen trichloride has a similar action but is much more reactive than chlorine, and therefore less of it is used. Benzoyl peroxide, after bleaching the coloring matter in the flour, remains as benzoic acid, and although the amount is small it is better that flour should not contain benzoic acid. Nitrogen peroxide, like the other bleachers, oxidizes the carotin in the flour. It is less reactive with proteins and fats than chlorine; it leaves nitrites in the flour, though very little. The committee regards nitrogen peroxide less unfavorably than the other bleaching agents. The substances used as 'improvers' are principally chlorine, nitrogen trichloride, acid calcium phosphate, acid ammonium phosphate, and persulphates, besides extracts of malt and wheat germ. It is claimed that "improvers' enhance the natural baking qualities of flour by yielding well risen loaves of good volume and symmetry, of satisfactory texture, and of even aeration. "Strength' is the term applied to flours possessing this character, and it depends on the qualities of the contained gluten. Some wheats are "weak," but the properties of the gluten can be altered by the addition of certain salts and acids. It is claimed that by the use of "improvers" a more varied supply of wheats can be used and blended, and a flour of uniform baking quality thus maintained. It is claimed also that the "improver" promotes the growth of yeast and so improves aeration. How improvers act is more difficult to define; one important factor is the degree of acidity. It is known, for example, that acid phosphates cause dispersed gluten to cohere, but another explanation ascribes the gluten change to oxidation.

The committee considers that a staple and indispensable foodstuff such as flour should be jealously guarded against unnecessary treatment with foreign substances but is not prepared, on the present knowledge available, to recommend the complete elimination of the bleaching agents and improvers. It advises that chlorine, nitrogen trichloride, and benzoyl peroxide should be forbidden. It should be compulsory for the manufacturers of chemical substances for use either as bleaching agents or as improvers or both to declare the nature of the ingredients of which they are composed, and that millers should be required to inform their customers whether their flour has undergone a process of chemical bleaching or improving or both, and if so, with what substances and in what proportion.

Bacteria Cause of Stone Decay

A new sphere of the destructive activity of bacteria has been discovered. The report of the stone preservation committee has been submitted to the building research board of the department of scientific and industrial research. Broadly speaking, this study has two aspects (*a*) chemical, physical and geological, and (*b*) biologic Mr Scott Russell was appointed to carry out the first series of investigations, and arrangements were made for Asst Prof S G Paine of the Imperial College of Science and Technology to undertake work with a view to determining whether there was sufficient evidence in favor of the theory that living organisms play a substantial part in stone decay to warrant more extended investigations in that direction Mr Scott Russell set himself at the outset to the perfecting of a method of cutting and mounting thin sections of specimens of decayed stone He used a synthetic resin which in liquid form impregnated the specimen at ordinary temperatures and which could then be converted into an infusible solid without causing appreciable distortion Many difficulties were encountered A method has, however, now been developed satisfactorily It appears that the microstructure of building stones is of primary importance and that the distribution of the pores in the stone is a preponderating factor in determining the rate of attack It was realized from the first that the investigation of the biologic activity in such a specialized medium as was presented by stone would call for new methods of bacteriologic technic A good beginning had been made in this direction and it was now possible to determine the actual bacterial content of different kinds of stone and of the same kind of stone under different degrees of weathering It had been established that stone apparently sound, might contain bacteria in considerable numbers, that, in fact, micro-organisms are present in the stone quarry to a depth of 2 feet below the quarry face This emphasized the possibility that investigation of anaerobic bacterial activity might be of as great importance as investigation of aerobic activity, if not indeed greater Experiments showed that different samples of weathered stone when incubated under these two conditions might behave very differently, the rate of growth of the organism in one sample might be enhanced by anaerobic conditions while in another exactly the reverse phenomenon might be shown The conditions prevailing in various samples of weathered stone were thus found to give rise to varying floras Apart from these variations the flora of stones collected in widely different localities exhibited a close general similarity The fact emerged that stone floras were limited to a small number of species so far only twelve had been observed These have been isolated and maintained in pure culture and are now under investigation, culturally and physiologically with a view to the appraisal of their importance in the processes of stone decay It is not yet possible to say whether bacteria play an important part in the processes of stone decay On isolating the bacteria from a certain specimen of weathered stone, the colonies which developed on the plate were all of one kind This fact, sufficiently significant in itself, was rendered still more so when, on investigation of the characteristics of this species, it was found capable of making luxuriant growth on an artificial medium so poor in organic food material that the life of other bacteria was barely supported

The Treatment of Hydrophobia in Calcutta

The second annual report of the Pasteur Institute in Calcutta is important because of the large number of cases of hydrophobia treated It deals with the year 1925, when 5,585 patients attended, of whom three fourths went through a course of antirabic treatment None of the 247 Europeans or Anglo Indians who underwent treatment died, but thirty three of the 3,921 Indians succumbed However, the conditions were much more favorable in the former Half the Europeans were no more than licked by the rabid animal, only 17 per cent of them had deep bites, none were bitten by a jackal, and 82 per cent came for treatment within a week On the other hand in 98 8 per cent of the Indians the skin was broken; 46 per cent were bitten deeply, in 33 per cent, the bite was of a jackal, and more than one third did not reach the institute until a week or longer had elapsed Sixteen of them developed hydrophobia either during the course of treatment or within fifteen days from its completion, and therefore can hardly be considered to be failures of treatment, but the remaining seventeen, who developed symptoms later than this, are set down as actual failures of treatment

PARIS

(From Our Regular Correspondent)

May 11, 1927.

The Congress of Red Cross Representatives

An assembly of directors of Red Cross societies was held in Paris, May 4 at the headquarters of the league (2 Avenue Velasquez), and the session was continued for nearly a week Fifty four nations were represented No international assembly of Red Cross societies has brought together, in recent years so many distinguished personages M Thiebaut announced that the French Red Cross Society, of which he is the secretary, had decided to send financial aid and antityphoid vaccine for the flood sufferers of the Mississippi Valley M Mortoft expressed thanks, in the name of the Red Cross Society and the government of Bulgaria, to the Red Cross societies who contributed for the benefit of Bulgarian refugees Colonel Draudt, vice president of the German Red Cross, made a statement in the name of his society "The German Red Cross Society has been able fully to appreciate, during recent years, the value of ties, uniting peoples, based not on the fragile supports of politics but secured through the more lasting bonds of human sentiment. The Red Cross Society constitutes such a bond—the greatest in the world" The council adopted a resolution which proposes the holding of a unified international conference every four years and a session, every two years, of the council of directors It was adopted by 39 votes to 7, the latter figure representing the Red Cross societies of the Scandinavian countries The council of directors reelected its staff of officers as follows Hon John Barton Payne, president, General Pau, honorary vice president, MM Kawal (Japan), Comill (Cuba) and Colonel Draudt (Germany), vice presidents The new members of the executive committee are M Geoffroy (France), Sir Arthur Stanley (Great Britain), Senator Ciraolo (Italy), Mr Athanasaki (Greece), Miss Masarykova (Czechoslovakia) and Professor Calderon (Columbia)

The International Conference on Rabies

The International Conference on Rabies, which was held recently at the Pasteur Institute in Paris, has not published its conclusions promptly because many members have been obliged to await the outcome of research The conference was divided into four subcommittees, the first of which, presided over by M Krauss and Bordet, studied, after a paper by A Marie, the nature of the virus of rabies The subcommittee concluded it was not in a position to decide whether the Negri bodies represent a form of bacteria or a reaction of the nerve cell The second subcommittee, presided over by MM Bujwid and MacKendrick, and the third headed by MM Pfeiffer and Zlatogaroff, studied, at first separately, then in collaboration, vaccinal treatment and postvaccinal accidents The papers were presented by M A Marie and M Remlinger The conclusion was reached that the technic introduced by Pasteur, forty-one years ago, was not susceptible of essential improvement The living virus used by Pasteur is preferable to the killed virus, and is harmless Virus that has been sterilized or attenuated by ether or phenol (carbolic acid) is not acceptable, except in vast regions in which communications are few and conservation of the living virus for a long period is difficult The researchers were unable to determine the causes of post-vaccinal accidents. There appear to be several causes, some accidents being attributable to age, some to overfatigue, some to syphilis, some to nervous conditions, as is the case with the intellectuals. Accidents are less frequent with glycerinated spinal cord and phenolized vaccine. There was a difference of opinion on the question of applying antirabic treatment to a person whose skin has been contaminated by the saliva of a hydrophobic animal or person, without breaking the skin. The conference passed a resolution recommending that the health section of the League of Nations make arrangements with one or more institutes for the organization of control, at regular intervals, of the various strains of virus and for the establishment of a standard virus of high immunizing potency. These institutes should send to the League of Nations their statistics on the patients vaccinated by them after an observation period of six months in each case. The fourth subcommittee, presided over by MM. Di Vestea and Kitejima, with M. Vallée delegated to read the paper, studied preventive vaccination of animals. In spite of the large number of favorable cases reported thus far, the committee did not think that the time had come to propose a modification of present sanitary legislation. It did, however, recommend preventive vaccination of the dog, each year, in the antirabic institutes and the veterinary schools, together with inspection of the dog, at the end of four months, by a veterinarian, and the keeping of a regular list of vaccinated subjects. The vaccination of animals other than domestic carnivora is not feasible, except in regions in which an epidemic may be raging with intensity. It is sufficient, when a subject is bitten, to apply vaccination of the subject within the first four days, or before the tenth day, at the latest.

Meeting of the International Bureau of Public Health

The special 1927 session of the permanent committee of the International Bureau of Public Health has just opened in Paris under the chairmanship of the Belgian delegate, M. Velghe. The session dealt with questions pertaining to sanitary agreements, chief among which was the international sanitary convention signed at Paris, June 21, 1926. A plan was considered for the organization of an information service on sanitary matters, with the collaboration of other international organizations, such as the bureau of the Far East of the League of Nations, located at Singapore, and the Pan-American sanitary bureau in Washington. The committee occupied itself further with the carrying out of the international arrangement that was signed, Dec. 1, 1924, the object of which is to provide sailors of the merchant marine who have venereal disease with gratuitous treatment in the chief ports of all countries. Other questions discussed at the session concerned the status of physicians on board merchant vessels, the sending by wireless of information as to quarantine regulations, the mental sequels of epidemic encephalitis, the epidemiology of the plague, the conservation of virus in wild rodents (South Africa, Russia, Siberia, California), and the possibility of united international action against such diseases as tuberculosis and cancer.

The Sale of Tuberculosis Seals

The president of the republic continues to be greatly interested in the sale of tuberculosis seals. M. Doumergue has given a beautiful Sèvres vase to the Comité national de défense contre la tuberculose, to be bestowed on the department of France that was most active in promoting the sale of health seals.

The Antirachitic Action of Cod Liver Oil

From a study by Dr. Simon, presented as an inaugural thesis at the Faculté de Paris, it appears that the antirachitic potency of cod liver oils is variable and that the causes of the variability are still unexplained. Some oils are entirely inactive, though they give the same physicochemical reactions as the others and meet the conditions demanded by the pharmacopeia. The color is not of significance. Some oils even cause an exacerbation of the rachitic process. These are usually recognizable by the fact that they cause, at the same time, digestive disturbances. By filtration the harmful principle can be eliminated. M. Simon holds that the only reliable means of controlling the efficacy of cod liver oils is a biologic test made on rats in which rachitic symptoms have been experimentally induced.

BELGIUM

(From Our Regular Correspondent)

April 2, 1927.

Suspension of Right to Practice Medicine

For the first time in Belgian history, a judgment of the correctional court (Brussels) provides that a physician shall be deprived, for the space of one year, of the right to practice the art of healing. The sentence is imposed on a practitioner who unnecessarily prescribed morphine in such a manner as to "create, maintain or aggravate a morphinomania." The sentence includes a fine of 30,000 francs.

Vocational Guidance

The Institut des hautes études of Belgium has recently added to the courses in ergology (1) systematic instruction in occupational selection and recuperation, under the direction of Dr. Paul Sillier and José Drabs, and (2) a course in psychotechnics in connection with occupational guidance, selection and recuperation, under the direction of M. José Drabs. These courses are intended more especially for engineers, physicians in factories, labor inspectors, candidates for employment as vocational guidance experts, managers of labor organizations, and members of instructional corps.

Industrial Medicine

Before the Société belge de médecine et de chirurgie Dr. Stassen has presented a study on the adaptation of the medical profession to the conditions of modern industry. He brought out the rôle of the physician in the economy of large modern factories. After giving an account of the development of medical organization in the coal mining region about Liége, he referred to the crusade against nystagmus and ancylostomiasis. These diseases have almost disappeared. Then he described the progress made in surgical services. Infection of wounds is the most important cause of disablement, and the results of the campaign against infection have been excellent. Whereas, in 1907, it was estimated that 40 per cent of lacerations and contusions of the fingers with openings in the flexor tendon sheaths developed infections, in 1910, the percentage had fallen to 10, and, in 1914, to 5. After the war, infections resulting from the opening of tendon sheaths fell below 3 per cent in 1920, to 1 per cent in 1921, to 0.7 per cent in 1922-1923, and they scarcely amounted to 0.2 per cent in 1924-1925.

Investigations as to the causes of accidents and joint researches carried out by the medical and the technical services may play an important part in the prevention of accidents.

Previous to 1906, in certain coal-mining regions the annual death rate from accident was 2 per thousand among the miners. During the period 1906-1909, the proportion was 1.8 per thousand; from 1910-1913 it dropped to 0.9 per thousand, and from 1920-1925 to 0.3 per thousand. In the coal mines in which preventive measures have not been organized, the yearly proportion of fatal accidents has remained 1 per thousand.

The organization of these services has decreased the number of days that the mines have been closed down. The figures express a definite economic value of the organization of medical aid in the industries.

Every coal miner in 1907 lost from accidents five days' work each year; in 1920-1925, only one day. For 10,000 workmen this represents a gain of 40,000 working days annually.

Prenuptial Examinations in the Grand Duchy of Luxemburg

Frequent reference has been made to the attempts of Dr. Govaerts to organize a system of prenuptial examinations in Belgium. Public opinion is interesting itself more and more in this question. In the Grand Duchy of Luxemburg, the projected law is based on the principle that the state is vitally interested in opposing the union of defectives, in order to prevent them from producing a degenerate progeny that will become a charge on the state. Taking this view of the matter, the state is justified in demanding that couples shall undergo a medical examination before marriage, although it is not necessary that the certificate issued them shall specify the exact nature of a disease from which one or the other applicant may be suffering. It is sufficient that they have consulted a physician in regard to the health aspects of their prospective union.

If the legislature accepts this view of the matter, it will stipulate that no civil officer may perform a marriage ceremony without requiring the presentation of a medical certificate dated within the last three days.

Sanitary Organization in the Belgian Congo Region

Dr. Broden gave recently a survey of the sanitary organization in the Belgian Congo region. The sanitary corps is composed of physicians attached to the state service. The laboratory physicians and the medical hygienists constitute a sort of staff charged with the supervision of the sanitary affairs of the colony. The work is not merely of an administrative nature, for the various laboratories at Leopoldville, Stanleyville, Elizabethville and Kitega are centers of research. In addition, there are the resident physicians whose mission it is to guard the health of the Europeans and the natives. Each center, no matter how unimportant, has a hospital with special departments for the natives. To each hospital several physicians are permanently attached, while others have itinerant missions that require them to cover assigned circuits. In the regions especially affected by trypanosomiasis special missions have been established with the object of checking the progress of the disease.

The hundred physicians attached to the Congo services all hold diplomas issued by the Ecole de médecine tropicale in Brussels. Pharmacists and sanitary employees are recruited from among Europeans who have sufficient training to apply hygienic treatment. These sanitary employees are trained in a special department of the Ecole de médecine tropicale before being sent to the Congo, where they can improve their knowledge through work in the colonial laboratories. There are at present fifty-two such sanitary employees attached to the Congo medical services. In addition there are volunteer nurses and nurses attached to the various religious orders. Nevertheless, this organization, raised to as high a standard as may be, is insufficient and the government therefore aids the auxiliary service that has been developed through the religious missions. The Ecole de médecine tropicale has likewise given medical training to prospective missionaries.

The missions have established twenty-five modern hospitals, some of which are models. The principal commercial and industrial centers are provided with sanitary stations, in which more than seventy-five physicians are engaged. Recently the committee constituted for the promotion of sanitary work has collected 4,000,000 francs ($160,000) with which to improve sanitary conditions in the Belgian Congo region. About a year ago, a branch of the Red Cross was established in the colony, and, within a period of four months, nearly 6,000 natives have been given medical examinations. The Oeuvre de l'enfance, a child welfare society, has likewise saved many lives in Africa.

The International Congress of Urology

The third Congress of the International Society of Urology will be held in Brussels, August 3-6, under the chairmanship of Prof. Jean Verhoogen. The three main topics on the program are: (1) the comparative value of the various methods of examining the blood and the urine in urologic surgery, the main speakers being Chabanier, Paris; Kojen, Belgrade, and Quinby, Boston; (2) treatment of tumors of the bladder by physical agents, the chief speakers being Beer, New York; Fryszman, Warsaw, and Heitz-Boyer, Paris, and (3) treatment of tuberculosis of the genitalia, the principal papers to be given by Barney, Boston; Gamberini, Bologna, and K Walker, London. For information concerning the congres application may be made to Dr. Jean De Smeth, 126 Boul vard de Waterloo, Brussels.

BERLIN

(From Our Regular Correspondent)

May 14, 1927.

Vital Statistics of Berlin in 1926

In 1925 there were only 35,092 marriages in Berlin; in 1926 the number rose to 36,593. The number of marriages per thousand of population was 7.8 in 1924, 8.7 in 1925, and 8.9 in 1926. The number of marriages contracted in 1926 was only slightly higher than the annual number during the prewar period. The birth rate has been affected in just the opposite manner. Whereas for the years 1923, 1924 and 1925 a slow increase in the number of living births was observable, in 1926 there was a slight decrease over the figures for the previous year (45,082 as against 47,071). The figures for the two years are accordingly 11.7 and 11.0 per thousand of population. Compared with the number of living births in 1913 (76,700), the figures for 1926 indicate a decrease for 1926 of about 40 per cent.

The number of deaths has decreased slightly; namely, from 45,651 in 1925 to 45,371 in 1926. Since, at the same time, there was an increase of the population, the death rate per thousand of population dropped from 11.3 in 1925 to 11.1 in 1926. The downward trend observable in the death rate of Berlin since 1922 did not suffer, therefore, any interruption in 1926.

The natural growth of Berlin, since, during the course of a year, the birth rate remains essentially constant, depends to a great extent on the fluctuations in the mortality. Although for the year 1925, as a whole, there was an excess of births over deaths amounting to 1,420, in the last three months of the year the reverse was true: the number of deaths exceeded the number of births. Only during the months from May to September, 1926, was there an excess of births over deaths, amounting to 1,054, so that the excess of deaths over births for the entire year amounted to 289.

Medical Researches on Mummies

In the *Münchener medizinische Wochenschrift*, Dr. Arnold Sack of Heidelberg gives an account of the results of the pathologic examination of not less than 30,000 Egyptian mummies, the main purpose of which was the discovery of pathologic changes. The peculiar religion of the ancient Egyptians, which taught that, after death, the human soul began a series of migrations extending over many thousands of years, whereupon it would return to the body of the deceased, is the fundamental reason why we still have preserved, entirely unchanged, a countless number of mummified bodies of persons who lived on the Nile during the reigns of the Pharaohs, three and four thousand years ago and longer. It was the first duty of every pious Egyptian to provide, while living, for the careful mummification and worthy burial of his body, in order that his existence, after death, in the world beyond might be happy and more beautiful.

For the medical investigator, there is interest in examination of mummies for traces of pathologic changes of any kind, in order to gain an insight into the condition of health among the ancient Egyptians, who are known to have had a comparatively highly developed art of healing.

Marked anatomic malformations and changes were, of course, the easiest thing to discover. For example, on the mummy of Pharaoh Siptah, of the nineteenth dynasty, a typical club foot was found. Numerous bone fractures were discovered, especially of the forearm; on the mummies in question there were, in some cases, artfully contrived splints. Bladder stones were found in mummies dating back to periods preceding the first dynasty. Kidney stones were found only as far back as 3200 B. C. In a mummy of the fifteenth dynasty a case of tuberculosis of the spine was established. Cancerous ulcers were not found until the Byzantine period was reached. Gouty changes were discovered in the mummy of an aged man. The feet especially were involved, and, more particularly, the great toes. The knee joints and the patellar ligaments were markedly penetrated with a white substance. White, chalklike deposits, which on chemical examination gave the typical reactions to uric acid, were found in the wrist and arm joints.

The observations made on the teeth of mummies are very interesting. In the oldest periods bad teeth were rare and in the poor population bad teeth were lacking. They were comparatively frequent, however, in the bodies of the kings. The 500 bodies of Egyptians of the uppermost class, which were excavated near Gizeh, presented tartar formation and dental caries to an extent almost equal to that of the modern European.

In the mummy of an Ammon priestess of the twenty-first dynasty an extensive pelvic abscess was found, and in the face of the mummy of Rameses V a peculiar skin change was noted which resembled smallpox scars.

The most important result for the science of medicine was the fact that changes indicative of syphilis could not be found on the mummies, which constitutes further evidence for the belief that syphilis was unknown to the ancient world. The mummies furnish likewise valuable material for the study of leprosy. The only case of leprosy that could be found in a mummy dated from the late Christian epoch, which strengthens the assumption that the leprosy of the Jews of biblical times, "*zaraath*," has nothing to do with genuine leprosy—that the leprosy of ancient times was a different disease the exact nature of which can be explained only by further researches in the field of historical medicine.

Marriages

Emmett P. North to Carolyn Tweedie, both of St. Louis, at Washington, D. C., May 19.

Jay W. Carter, Greenup, Ky., to Mrs. Minnie Russell of Johnson City, Tenn., at Huntington, W. Va., April 25.

Benjamin Huger Rutledge, Jr., Charleston, S. C., to Miss Eleanor Louise Oliver of Baltimore, May 28.

Everett A. King to Miss Margaret Simminger, both of Fort Wayne, Ind., May 21.

Charles F. Harmon to Miss Irene E. Medaris, both of Springfield, Ill., May 18.

Deaths

Abraham Zingher, New York, was asphyxiated in the laboratory of the Willard Parker Hospital June 5, when a gas burner became disconnected while he slept in a chair after work. Born in Roumania, in 1885. Dr. Zingher received his medical degree from Cornell University Medical College in 1908, and his Ph.D. from New York University in 1917. He was for several years an intern at Mount Sinai Hospital and chief of the outdoor medical service. He was assistant professor of bacteriology at University and Bellevue Hospital Medical College and clinical professor of pediatrics at the New York Polyclinic; was on the staff of the Willard Parker Hospital; a member of the Medical Society of the State of New York, the American Association of Pathologists and Bacteriologists, of the American Association of Immunologists and various other scientific societies. Dr. Zingher served in France during the World War. As assistant director of the bureau of laboratories of the New York City department of health he had a prominent part in the great work of immunizing school children against diphtheria; he will long be remembered as an arduous worker in various other communities in immunizing children against diphtheria and scarlet fever. He was among the foremost immunologists in the country, and the author of many scientific papers.

Timothy Joseph Shanahan ⊕ Boston; Harvard University Medical School, Boston, 1905; formerly assistant in laryngology, Tufts College Medical School; member of the American Academy of Ophthalmology and Oto-Laryngology and the New England Otological and Laryngological Society; on the staffs of the Somerville (Mass.) Hospital, the Milford (Mass.) Hospital, the Carney Hospital, St. Mary's Infant Asylum and the Massachusetts Eye and Ear Infirmary, Boston; aged 48; died suddenly, May 10, at his home in Somerville, of heart disease.

Percival Butler McCutchon, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1879; member and formerly secretary of the Louisiana State Medical Society; past president and secretary of the Orleans Parish Medical Society; at one time sanitary inspector for the state board of health; aged 75; died, May 12, at the Touro Infirmary, of acute intestinal obstruction.

Henry Isaiah Dorr ⊕ Winchester, Mass.; Jefferson Medical College of Philadelphia, 1883; member of the Medical Society of the State of Pennsylvania, and the Associated Anesthetists of the United States and Canada; also a dentist; Civil War veteran; aged 82; died, April 24, of angina pectoris.

Logan D. Dameron, Phoenix, Ariz.; Hospital College of Medicine, Medical Department Central University of Kentucky, Louisville, 1891; member of the Arizona State Medical Association; health officer of Phoenix; aged 69; died, March 11, at Los Angeles, of cerebral hemorrhage.

Samuel E. Mowery, Mechanicsburg, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1895; member of the Medical Society of the State of Pennsylvania; past president of the Cumberland County Medical Society; aged 65; died, May 1, of carcinoma of the liver.

Thomas E. Spalding, Lockport, N. Y.; University of Buffalo School of Medicine, 1901; member of the Medical Society of the State of New York; health officer of Lockport and formerly health officer of Salamanca; aged 47; died, April 27, of coronary embolism and endocarditis.

Henry Lee Crook, Jackson, Miss.; Louisville (Ky.) Medical College, 1891; member of the Mississippi State Medical Association; formerly county health officer; aged 58; died, May 5, at a local hospital, of pulmonary embolism, following a prostatectomy.

John Edward Hollingsworth, Vandalia, Mo.; Hospital College of Medicine, Medical Department Central University of Kentucky, Louisville, 1890; member of the Missouri State Medical Association; aged 65; died recently, of multiple sclerosis.

Florena Gates Rich, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1925; on the staff of the Charity Hospital; aged 29; died, May 12, at the Touro Infirmary, of acute leukemia and pericarditis.

Jacob Lorenzo Loutzenhiser, Windom, Kan.; University Medical College of Kansas City, Mo., 1905; also a druggist; served during the World War; aged 44; died, May 2, at a hospital in McPherson, of cerebral hemorrhage.

Thomas Joshua Bennett ⊕ Austin, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1883; past president of the State Medical Association of Texas; aged 73; died, March 16, of angina pectoris.

Lawrence A. Baker, Middlebourne, W. Va ; Maryland Medical College, Baltimore, 1905; aged 49; died, May 15, at the Ohio Valley General Hospital, Wheeling, of chronic nephritis, chronic cholecystitis and myocarditis

Henry T. Coggeshall, New York; Harvard University Medical School, Boston, 1883, member of the Medical Society of the State of New York; aged 68, died, May 24, of uremia and carcinoma of the bladder.

Elbridge Gerry Minar ⊕ Mannsville, N. Y.; Medical Department of the University of the City of New York, 1883, aged 67; died, May 16, at the Good Samaritan Hospital, Watertown, of heart disease.

Homer Valmore Halbert, Chicago; Hahnemann Medical College and Hospital, Chicago, 1887; formerly clinical professor of internal medicine at his alma mater, aged 68, died, May 28, of angina pectoris.

Richard Clarke Baker, Kansas City, Kan.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1890; member of the Kansas Medical Society; aged 65; died in May, of heart disease

Shepard Bassett Clark, Beaver Dam N. Y ; Bellevue Hospital Medical College, New York, 1889, member of the Medical Society of the State of New York; aged 59, died, May 16, of heart disease

Harry Marbury Tayloe, Hague, Va.; George Washington University Medical School, Washington, D C., 1908; member of the Medical Society of Virginia, aged 51; died, April 21, of pneumonia.

Frank T. Carmack, Iuka, Miss , Vanderbilt University School of Medicine, Nashville, Tenn , 1880, member of the Mississippi State Medical Association; aged 70, died, April 2, of paralysis

Robert L. Pipkin, Springfield, Mo ; Missouri Medical College, St Louis, 1894, member of the Missouri State Medical Association, aged 58, died suddenly, May 4, of cerebral hemorrhage

Edward Scanlon Sullivan, Concord, N H : Harvard University Medical School, Boston, 1919, member of the New Hampshire Medical Society; aged 35, died, April 9, of pneumonia

DeWitt H. McGraw, Binghamton, N Y : New York Homeopathic Medical College and Hospital, 1888, aged 66; died, May 9, of carcinoma of the face

James North ⊕ Margate City, N J ; Jefferson Medical College of Philadelphia, 1880, formerly a dentist, aged 71; died, May 13, of tuberculosis of the larynx

Frank Eugene McElree ⊕ Greenville, Pa ; Western Reserve University School of Medicine, Cleveland, 1909, aged 46; died, April 29, of angina pectoris.

Henry Clay Dunavant, Osceola, Ark ; University of Nashville Medical Department, 1873; Confederate veteran; aged 83, died, May 2, of acidosis

Judson Carey Panter, Chicago; Rush Medical College, Chicago, 1870, aged 77, died, May 6, at his home in Evanston, Ill, of cerebral hemorrhage.

John E. Mapp, Keller, Va ; Washington University School of Medicine, Baltimore, 1868; aged 81; died, April 30, of cirrhosis of the liver.

George Hugh Peddle, Perry, N. Y; College of Physicians and Surgeons, Baltimore, 1891; aged 64; died, May 4, of cerebral hemorrhage.

Harry Doutrick, West Palm Beach, Fla.; Louisville (Ky.) Medical College, 1890; aged 73; died, April 9, of chronic cholecystitis.

Emma J. Welty, Portland, Ore.; Boston University School of Medicine, 1880; aged 70; died, May 2, of carcinoma of the lung

B. Franklin Richards, Denver; California Eclectic Medical College, Los Angeles, 1903; aged 75; died, April 22, of angina pectoris.

Augustus Samuel Clayton, Emerson, Ark (licensed, Arkansas, 1903); Confederate veteran; aged 94; died, May 5, of pleurisy.

Benjamin J. McCleskey, Atlanta, Miss. (licensed, Mississippi, year unknown); aged 81; died, May 11, of heart disease.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

THE FLORAZONA FRAUD

The Post Office Debars Another Fake "Fat Cure" from the United States Mails

On May 24, 1927, the Postmaster General issued a fraud order against the Florazona Corporation of New York City, debarring it from the use of the mails, and notifying postmasters to return to their senders all letters addressed to the Florazona Corporation, with the word "Fraudulent" plainly written or stamped on the outside of such letters.

"Bathe and Grow Thin. Be Fashionable. Be Healthy. Be Comfortable."

"Lose a pound a day."

"Simply dissolve Florazona, a fragrant powder in your bath, and ½ lb. to 1 lb. of excess fat just melts away through the pores!"

"This great scientific European gland discovery is recommended by physicians, nurses and thousands of delighted users. Contains no epsom salts or alum"

Reduce!
...A POUND A DAY NATURE'S WAY
FLORAZONA
Absolutely Harmless
Money Back
Reduce!
8 to 15 pounds in only 2 weeks
No Exercise, No Diets, No Drugs
FLORAZONA

These and similar blurbs introduced to the "stylish-stouts" the latest piece of hokum in the "obesity cure" field. It is hard to understand how the public can be so ignorant of the most elementary facts of physiology as to believe that obesity may be reduced by putting something in the bath water. Yet the perennial popularity of this particular type of "obesity cure" shows that such ignorance is common.

On March 23, 1927, the Florazona Corporation of New York City was called on by the Post Office department to show cause why a fraud order should not be issued against it. The case came up for hearing on May 16, when Mr. Jacob L. Grubel, a New York attorney, appeared in Washington to defend the concern. The promoters of the Florazona enterprise were not present, nor were any witnesses produced by their counsel.

It was brought out at the hearing that the Florazona Corporation was incorporated under the laws of the state of New York in 1922. The capital stock, consisting of 150 shares of no par value, was owned equally by M. Rosenberg, president and originator of the business, and M. Rubin, secretary and treasurer of the concern. These men operated the business with the assistance of one employee; no physicians, chemists or pharmacists were connected with the Florazona Corporation. The promoters admitted that the yearly advertising cost was estimated at $7,000 and the gross receipts were approximately $20,000 annually.

Florazona, when analyzed by the federal chemists in the Bureau of Chemistry, was found to be essentially sodium thiosulphate (the "hypo" of the photographers), with a small amount of baking soda and a trace of iodides and perfume. It was shown that the package of Florazona, which sold for $3.50, could be manufactured for about 17½ cents.

As is common in the advertising of fat-cure swindles, the advertisements stressed the claim that, when using Florazona, it was unnecessary to exercise or to diet. The Florazona slogan was: "No Exercise—No Diet—No Drugs." Yet, as is also usual in the sale of such fakes, after the purchaser had paid her money, she found that dieting was suggested. Thus:

> "Do not eat fat meats. Substitute bran, whole wheat or rye bread for white bread. . . . Cut down on sweets and candy."

The advertising booklet of the Florazona concern contained what purported to be a number of testimonials. None of these were dated, nor were the names of the persons who were supposed to have given them shown. The Post Office inspector who looked into this fraud was given what was claimed to be the correct names and addresses of some of the persons who had written these alleged testimonials. He communicated with them and each person who replied to the inspector's inquiry stated that she did not give any testimonial to the concern.

Dr. L. F. Kebler, physician and drug expert, testified in behalf of the government, and stated in effect that Florazona was absolutely worthless as a fat reducer. This testimony was not controverted in any way by the respondents. In view of this, Judge Horace J. Donnelly, solicitor for the Post Office Department, recommended in his memorandum to the Postmaster General that a fraud order be issued. It was issued as stated.

Correspondence

THAYER, CARROLL AND LAZEAR

To the Editor:—In the too generous editorial comment about me (The Journal, May 28, p. 1717), reference is made to my association with Carroll. It was not with Carroll but with my dear friend Lazear that I worked on the cultivation of the malarial parasites in *Anopheles maculipennis*. Lazear was a warm friend and associate. While I had met Carroll on a number of occasions, I had had little association with him before the work of the Yellow Fever Commission.

Reed, of course, was a warm friend of all of us who were at the Johns Hopkins Hospital in the year '90-'91. His keenness, his enthusiasm, his ability made a great impression on all of us, and during the few months that he spent in residence at the hospital he endeared himself greatly to every one.

It is one of my pleasantest memories that Reed was a member of Welch's postgraduate class in pathology to which in the winter of 1890-1891 I gave a few talks on the methods of examination of the blood. I confess that I have boasted on various occasions of having taught Reed how to examine blood, and have been proud to shine by the reflected light.

W. S. Thayer, M.D., Baltimore.

THE DUODENAL BUCKET

To the Editor:—In The Journal, March 19, I published a letter in which I had occasion to criticize Dr. Sylvan D. Manheim for failing to give me proper credit while using a bucket which I innovated as a basis for his improvement.

For the information of your readers and in justice to Dr. Manheim and myself, I wish to state that the dispute was referred for arbitration to a committee of three physicians from Mount Sinai Hospital who have decided that while I was first in the field with my bucket there was no evidence to show that Dr. Manheim deliberately infringed on my rights.

Moses Einhorn, M.D., New York.

"NEW BLOOD CONSTITUENTS"

To the Editor:—In the editorial entitled "New Blood Constituents" (The Journal, May 7, p. 1484), there appears a sentence from which it might be inferred that glutathione was found in blood for the first time by Brand and Sandberg. Glutathione in blood and its unquestionable identity with glutathione from other sources was first established by H. F. Holden working in the laboratory of Sir F. G. Hopkins at Cambridge (Holden, H. F.: *Biochem. J.* **19**:727, 1925).

Erwin Brand, Ph.D.,
Marta Sandberg, Ph.D.,
Division of Laboratories, Montefiore
Hospital, New York.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE CUNNINGHAM TANK TREATMENT

To the Editor:—I have been questioned recently in regard to a new treatment for diabetes, which, I believe, is in vogue in Kansas City. This treatment is described as a large chamber, somewhat like a calorimetric chamber, in which the patients live for a period of two or three weeks, and during that time they are supplied with air containing a high percentage of oxygen. I imagine that much of their popularity is due to the supposed cure of a prominent manufacturer, and plans are being made to erect such tanks in Cleveland. The theory advanced is that the high content of oxygen circulated in the blood causes regeneration of the defective elements of the pancreas. Have you any information on this subject? If so, I would appreciate it.

W. M. Sheppe, M.D., Wheeling, W. Va.

Answer.—Doubtless, the alleged new treatment is that used by Dr. O. J. Cunningham of Kansas City, Mo. For some eight years Dr. Cunningham has been treating certain conditions by putting patients in a tank, under air pressures varying from 10 to 50 pounds to the square inch above ordinary atmospheric pressure. Patients are kept in the tank from a few hours to a month. Dr. Cunningham's thesis is that diabetes mellitus, pernicious anemia and carcinoma are due to pathogenic bacteria of the anaerobic type, and that the oxygen content of the tissues is greatly increased when the patients are put in the tank containing the compressed air. Hence, in the doctor's opinion, the compressed air treatment is curative in certain cases of diabetes mellitus, pernicious anemia and even in some cases of apparently hopeless carcinoma.

We do not know of any independent work that has been done to substantiate Dr. Cunningham's observations, and the only publication that Dr. Cunningham himself has made seems to have been a short article in the April, 1927, issue of *Anesthesia and Analgesia*. From material that has come to our attention during the last few years, there is reason to believe that Dr. Cunningham has allowed enthusiasm to run away with judgment.

DERMATITIS VENENATA

To the Editor:—Any suggestion regarding the treatment of this case will be greatly appreciated: A woman, aged 40, Scotch, with one healthy child and no miscarriages, has had for the last two years, previous to the onset of menstruation, a condition closely resembling dermatitis venenata on both hands, sharply demarcated above the wrists. There is also bilateral tenderness over the region of the ovaries. As menstruation becomes well established, the local conditions gradually disappear. No abnormality of the pelvic organs has been observed. All treatment, including local (on the hands), organotherapy and sedatives, has failed to prevent the monthly recurrences. What is your opinion of autohemotherapy (intramuscular reinjection of the patient's own blood) during the height of an attack, or of irradiation or removal of ovaries? Please omit my name.

M.D., Chicago.

Answer.—A condition resembling dermatitis venenata, sharply limited to the hands and wrists, is likely to be dermatitis venenata but due to external irritants, the finding of which may be very difficult. A careful search should be made for them, and local treatment based on this assumption should be instituted The only internal disease in which this sharply defined dermatitis on the hands is likely to occur is pellagra There is no good reason to believe that such cases of dermatitis are ever due to ovarian dysfunction Radical treatment directed to the ovaries simply on a surmise based on the fact that the condition is apparently worse about the time of menstruation and that there is tenderness over the ovaries would be a grave proceeding on the weakest assumptions, and would be unwarranted practice Autohemotherapy has very little reputation among conservative dermatologists in such conditions

HAIR DYE

To the Editor —In The Journal, Jan 2, 1926 page 60, a formula for a hair dye using henna leaves was given I have tried this formula and find that when I use ammonia water as recommended to make a darker stain the hair fails to take the dye at all I shall appreciate it if you can tell me where the fault is I wish to make a dye that is darker than what henna alone will make yet I desire that it be harmless and will not stain the scalp Please omit my name

M D, Indiana

Answer —The dye should be applied as a wet dressing to hair that is already wet, and allowed to remain several hours Repeated applications are necessary for much effect A very small amount of ammonia should be added About 1 5 per cent of 10 per cent ammonia solution seems to be as helpful as a larger amount

TREATMENT OF PARALYSIS AGITANS

To the Editor —Could you suggest something to relieve the drawing sensation and spasticity of muscles in Parkinson s disease? The patient has been receiving morphine Phenobarbital causes complete paralysis The heart is very irritable to morphine Kindly omit my name

M D, Washington

Answer —Of all drugs, scopolamine hydrobromide is the most satisfactory in the treatment of the tremor and rigidity of Parkinson's disease If it causes so much dilatation of the pupils as to interfere with accommodation, it may be discontinued one day a week or oftener If too much dryness of the mouth is induced, pilocarpine may be given with it

USE OF TUBERCULIN

To the Editor —Is there any recognized treatment with tuberculin such as administration for a tonic effect, for any building up properties it may possess or as a prophylactic against tuberculosis? Is there any authority whatever for using it in this manner? Please omit name

M D, Ohio

Answer —The use of tuberculin has been generally abandoned in the treatment of tuberculosis of the lungs There are still some who believe that tuberculin has the values attributed to it by the earlier workers in the field However, there is no clinical proof that tuberculin possesses tonic or prophylactic properties

FLETCHERIZE"

To the Editor —What was the original meaning of the term 'to fletcherize'?

H S Hoffman, M D, Washington, D C

Answer —According to the Standard Dictionary, fletcherize means to masticate to the point of complete pulpefaction" Fletcherism is "a theory, advocated by Horace Fletcher, that perfect health requires and is maintained by complete mastication or a chewing of the food into pulp before it is swallowed" Fletcherism became a fad and consequently was overstressed For a time however, some genuine investigation was done along the lines suggested by Fletcher This side of the subject is outlined in 'The New Dietetics," by John Harvey Kellogg, Modern Medicine Publishing Company, Battle Creek Mich, 1921, beginning on page 80

DRESSING FOR BURNS'

To the Editor —The following formula is given in answer to numerous inquiries with reference to my article Dressing for Burns (The Journal, May 7, p 1483) Four ounces of pure gelatin dissolved in 1 gallon of water will moisten quite a quantity of gauze After the gauze is dried, it is immersed for a few minutes in solution of formaldehyde U S P, diluted to one half strength, to fix the gelatin The gauze is then washed, dried, packaged and sterilized Any good hospital can sterilize the gauze, as it is not injured by autoclaving

Book Notices

De Lamar Lectures, 1925 1926 By David Marine, Alice Hamilton, Francis Carter Wood, Frederick W Sears Thomas Adams, W G Smillie, Edward R Baldwin, Louis I Dublin, Joseph Goldberger, C R Stockard, Horace Lo Grasso, Robbins B Stoeckel Sir Arthur Newsholme The Johns Hopkins University School of Hygiene and Public Health Cloth Price, $5 Pp 220, with illustrations Baltimore Williams & Wilkins Company, 1927.

In 1920, the School of Hygiene and Public Health of Johns Hopkins University instituted its lectures in hygiene to carry out the wishes expressed by the will of Joseph R De Lamar to give to the people of the United States generally the benefits of increased knowledge concerning the prevention of sickness and disease, and also concerning conservation of health by proper food and diet It is impossible in the space of a brief review to list all these lectures or to discuss them critically They are all by writers recognized as experts in the fields concerned, and they discuss such important problems as industrial disease, cancer, rural hygiene, longevity, the body-constitution, prevention of accidents and similar topics The importance of these lectures is such that one would wish some plan had been devised for much wider circulation than is likely to be secured by mere collection in book form The extension of the material into the public press or into periodical literature would accomplish far more along the lines in which the donor wished, no doubt, to direct them

Der Baranysche Zeigeversuch Seine physiologischen Grundlagen und klinische Methodik Von Dr med Ernst Wodak Paper Price, 3 marks Pp 79, with 26 illustrations Berlin Urban & Schwarzenberg, 1927

This brochure covers in considerable detail the pointing method of Barány The author states, however, that he does not discuss the fallacies of the reaction but reserves them for a future date In discussing the psychophysiologic principles underlying the pointing reaction together with the labyrinthine factors, the author concludes that although the pointing reaction is of great clinical value it is not yet possible to localize definitely a lesion of the cerebellum by means of the reaction itself It would require a great deal of work to determine these facts After the first publications by Barany it was thought that the definite localization of cerebral lesions could easily be arrived at with the pointing reaction, but these must be held with considerable reservation This little book is a valuable addition to the study of the subject and will well repay those who are doing otologic and neurologic work to evaluate the pointing reaction It is true of many discoveries in the realm of medicine that at first too much is expected of a procedure that requires years of careful study on the part of numerous investigators before the real facts are thoroughly tested and definite conclusions drawn which will be of value in diagnosis and in the relief of diseases in various parts of the body Much credit is due a man like Barany for this pioneer work in a difficult field

Behaviorism By John B Watson Lecturer, the New School for Social Research Cloth Price, $3 Pp 251 New York W W Norton & Company, Inc, 1925

Psychology What It Has to Teach You About Yourself and Your World By Everett Dean Martin Cloth Price, $3 Pp 302 New York W W Norton & Company, Inc 1924

Dr J B Watson, noted throughout the country as a leader of the behavioristic school of human conduct, here presents in twelve lectures for the general public a guide to the entire subject The style is simple and direct, but the material is presented with sufficient scientific reference to establish clearly the basis on which the behavioristic school rests its banners The sections on the technic of the behavioristic school and its interpretations of human actions and habits are of great interest, particularly as they relate to everyday life A striking chapter is that devoted to personality, with reference to the means that have been taken for determining suitable occupation and similar subjects Several paragraphs on fakers in psychology expose to public gaze the type of charlatan who is scheming to thrive on the newer psychology

The volume by Everett Dean Martin is an attempt to tell a public audience in twenty lectures how psychology as a science is related to practical affairs in human life It is concerned not only with the older psychology, but also with the freudian views, the work of MacDougall, of William James and the behavioristic scheme of Dr Watson The section on propaganda and public opinion is both a guide to the mob mind and a warning as to how the demagogue uses it for his personal interests Again and again physicians have been told of the importance of the mind in relation to disease and of the necessity for the understanding of the fundamental facts of psychology to the progress of medicine The volume by Martin may be recommended as one by which the knowledge concerned may be easily acquired

Die Croon Vorlesungen uber Aufbau und Abbau des Nervensystems (Croonian Lectures on the Evolution and Dissolution of the Nervous System) Von J Hughlings Jackson Uebersetzt von Otto Sittig Paper Price, 6 60 marks Pp 137 Berlin S Karger, 1927

As these lectures were delivered by Hughlings Jackson in 1884, the German translation seems to be a bit belated However, the fact that they have been translated is not only a tribute to the genius of Jackson but also a decided credit to present-day German neurology Unfortunately, the writings of Jackson are not particularly lucid and his style not especially attractive and consequently his writings have been a long time in coming into their own This translation is accompanied page for page by the English text and it is to be hoped that not only many German neurologists but also many of those in England and America will profit by this publication of the lectures of one of the most remarkable thinkers who ever adorned the annals of medicine

The Metabolism of the Fasting Steer By Francis G Benedict, Director, Nutrition Laboratory, Carnegie Institution of Washington, and Ernest G Ritzman, Research Professor in Animal Nutrition, New Hampshire Agricultural Experiment Station Paper Pp 246, with illustrations Washington Carnegie Institution, 1927

This monograph presents a detailed study of a problem of practical as well as theoretical importance The practical aspect of the question is indicated in the following quotation from the introduction "In the management of domestic live stock, farmers of the United States have been educated to believe that regular and liberal feeding forms the basis of good economic practice This belief has not uncommonly led to the inference that animals deprived entirely of food, even for a relatively short time, would endure physical hardship, suffering and injury The error of such a conclusion is best illustrated by a consideration of the life habits of wild animals, such as the deer, which is also a ruminant Deer pass through long periods of deprivation, when food is scant, or sometimes entirely lacking, and on the whole survive in excellent shape, with remarkable vigor, unimpaired by such experiences." The steers were subjected to varying types of undernutrition, including complete fasting except for water, of periods of from four to fourteen days. After the second day of fasting no particular irritation or craving for food was shown, no sign of lacking vitality and energy, the steers appearing as strong and healthy even on the last day of the *fourteenth day fast* as in the earlier days of the fasting, but the fasting animals spent the larger portion of the time lying down. Rumination ceased after the second day. There was reduction in the basal metabolism progressively during the fast, and after the third day of complete fasting the respiratory quotient fell from the normal of unity to the lower level of 0.70, showing that the energy of the steers was derived solely from fat. There was no lowering of the body temperature produced by fasting. This study on fasting steers reveals essentially nothing new in comparison with data previously obtained on fasting men and other animals. A striking difference, however, appears in the steer, in comparison with other animals, in the high basal metabolism as figured on the square area of body surface. In the steer this is around 1,300 calories per square meter of body surface daily, in comparison with the average of 800 or 900 calories for man and other animals.

Le sixième sens. (Sens génésique). Organes de la génération. Fonction sexuelle. Aberrations génitales. Curiosités relatives aux seins. Par Docteur Cabanés. Cloth. Price, 12 francs. Pp. 259. Paris: E. le François, 1927.

Rabelaisian curiosities from a medical angle form the text of this book. The extraordinary birth of Gargantua is not vouched for by Dr. Cabanés, but he is quite positive as to a case reported in 1899 by Dr. Lermoyez of an almost equally active auditory canal. We learn from the book that the ancients went unclothed without shame; that the Jews, to avoid the heavy taxes levied on them by the early Romans, resorted to surgery to hide the marks of their circumcision which proclaimed them Jews; that men have been known to marry up to the age of 111 years; that Joseph Surrington, a Norwegian who died in 1797 at the age of 160 years, had become a father only nine years before his death; that girls of a tender age have given birth to children—the youngest mother recorded being 9½ years old; that it is the custom in certain countries for the mother of a new-born infant to rise the first day and for the father to take her place with the child, while neighbors and friends call to inquire for the father's health and to express their sympathy for his suffering. These are some of the less obscene curiosities related by Dr. Cabanés.

Preventive Medicine and Hygiene. By Milton J. Rosenau, Professor of Preventive Medicine and Hygiene, Harvard Medical School. With Chapters upon Mental Hygiene. By Abraham Myerson. Sewage and Garbage. By Gordon M. Fair. Vital Statistics. By John W. Trask. Statistical Methods. By Carl R. Doering. Conservation of Vision. By J. Herbert Waite. Fifth edition. Cloth. Price, $10. Pp. 1458, with 157 illustrations. New York: D. Appleton & Company, 1927.

The fifth edition of this volume is necessitated by numerous advances that have been made in the field of preventive medicine, particularly as concerns such topics as amebic dysentery, scarlet fever, epidemic encephalitis, tularemia, rickets and pellagra, and also because more and more attention is being given to mental hygiene. As Dr. Rosenau emphasizes in his preface, "The new subjects considered comprehensively for the first time in this book are the psychanalytic approach to sex hygiene, the prevention of cancer, the conservation of vision, periodic physical examinations, flukes and their relation to disease, granuloma inguinale, balantidial dysentery; also resuscitation, gas masks, statistical methods and practical points in public health administration." This book established itself as a standard in its field when first published, and succeeding editions have been quite up to the mark of previous ones. The collaborators are responsible for much additional material. In every way, the volume is an adequate reference to its subject.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits. Books listed in this department are not available for lending. Any information concerning them will be supplied on request.

Tuberculosis of the Lungs. A Practical Guide for General Practitioners. By H. Hyslop Thompson, M.D., D.P.H., County Medical Officer of Health and County Tuberculosis Officer for Hertfordshire, and A. P. Ford, M.R.C.S., L.R.C.P., D.P.H., Clinical Tuberculosis Officer and Deputy County Medical Officer of Health for Hertfordshire. Cloth. Price, $4. Pp. 179, with 30 illustrations. New York: William Wood & Company, 1927.

Another British guide to tuberculosis.

The Mystic Rose: A Study of Primitive Marriage and of Primitive Thought in Its Bearing on Marriage. By Ernest Crawley. In two volumes. Second edition revised and greatly enlarged by Theodore Besterman. Cloth. Price, $10 per set. Pp. 715. New York: Boni & Liveright, 1927.

Translation of ethnologic companion to Westermarck's history of marriage.

Declaration of Insanity Under Unconstitutional Law

(Torres et al v Gersdorff (Texas), 287 S W R 668)

The Court of Civil Appeals of Texas says, in this action to try title to certain real estate where it was a question whether one Mary Torres was insane in July, 1923, that it is a presumption of law that all men are sane, and the burden rests on the party pleading insanity to establish such insanity, but, when it is proved that a person has been legally adjudged to be insane, the presumption of insanity will continue until an adjudication of a return to reason has been made The burden of showing the restoration of reason rests on him who asserts it Mary Torres may have been insane in 1915, when the court in its judgment found her to have been insane, but, unless there was a legal adjudication of the fact of insanity by a constitutional tribunal under constitutional procedure, the judgment did not avail, and, in the absence of such judicial action, the legal presumption of sanity attaching to all citizens would still attach to her

It was alleged that Mary Torres was adjudged to be insane by the county court of Bexar County on or about July 21, 1915 The only law in effect at that time authorizing the adjudication of insanity was the act of 1913, which provided for a commission, composed in whole or in part of physicians, to be appointed by the county judge, to whom was given the power to pass on the sanity or insanity of persons brought before it That law was subsequently held by the Supreme Court of Texas to be unconstitutional No other law was in effect when Mary Torres was declared a lunatic, and consequently she must have been declared a lunatic under that unconstitutional law Her incarceration in the insane asylum was therefore illegal and void The declaration of the trial court in its orders and judgment could have had no higher authority than the illegal and void report by the commissioners appointed by the county judge in 1915 All the presumptions must be indulged that Mary Torres was confined in the insane asylum under the terms of the act of 1913, because it was not declared unconstitutional by the supreme court until 1917 The admissions of the guardian ad litem as to the state of mind of his ward could have no force or effect in a court of law, equity and justice He had no authority to admit any fact that would undermine and destroy the defense of the ward that he had been appointed to defend

Typhoid Contracted in Epidemic Not Compensable

(Pattiani v State Industrial Accident Commission et al (Calif), 250 Pac R 864)

The Supreme Court of California, in affirming an order of the state industrial accident commission denying the petitioner compensation, says that, in pursuance of his employment he left San Francisco, Nov 2, 1924, visited a number of cities, returning to San Francisco, Dec 2, 1924 While in the city of New York he lived at a well known hotel for five days and visited a number of business establishments within the scope of his instructions He testified that while there, on or about November 17, and also about three days later, he ate raw oysters at the hotel After leaving New York he found himself ill, the illness continuing until he arrived in San Francisco and for some time thereafter, his ailment being diagnosed as typhoid He applied to the industrial accident commission for an award, and the commission found that while he was in New York he contracted and became ill with typhoid, that at the time of his visit in that city there was prevalent in that locality an epidemic of typhoid, that the evidence did not establish as a fact that the epidemic was caused or aggravated by contaminated oysters, that the fact that he was required by his employment to visit or sojourn in a locality where there was an epidemic or disease did not constitute a special exposure arising out of the employment, but was in fact an exposure or risk of the commonalty in general, and not peculiar to or characteristic of the employment Based on that finding the commission denied an award

The effect of certain denials of writs of review by this court is that of holding that in order to a recovery of an award by an employee who, in the course of the performance of his duties as such, whether in the immediate place of his employment or in whatever place he may be in pursuance of his employer's directions, contracts a contagious or infectious disorder, he must, in order to make such recovery, establish the fact that he was subjected to some special exposure in excess of that of the commonalty, and in the absence of such showing of special exposure the illness or death of the employee can not be said to have been proximately caused by injury arising out of his employment In the instant case no direct connection between the employee and his infection with the disease of typhoid was shown, on the contrary, his attempted proof of such connection was negatived by the commission in its finding that the evidence did not establish the fact that the epidemic of typhoid in New York was caused or aggravated by contaminated oysters No other direct contact between him and the existing epidemic of typhoid in New York during the brief period of his visit there being shown, this court is of the opinion that the commission was correct in holding that the evidence before it was insufficient to show a special exposure arising out of the employment and that the mere fact that there was an epidemic of typhoid in New York during the period of his visit there constituted an exposure or risk of the commonalty in general and was not peculiar to or characteristic of his employment, and for that reason compensation to him was properly denied

In arriving at its conclusion in the instant case this court is not to be understood as announcing a rule which might be applicable to the case wherein an employer directs his employee to go to a place wherein, with the knowledge of the employer there is prevalent an infectious or contagious disease There was no such showing made in the case before the court

An Injury to Patient Not Chargeable to Physician

(Hanners v Salmon (Ky) 288 S W R 307)

The Court of Appeals of Kentucky says that the plaintiff alleged that, eight weeks after his left leg was fractured between the knee and the hip joint and he was taken to a hospital where he received treatment by the defendant, the latter directed that he be removed from the bed and placed in an invalid chair, that on the third day that this was done the leg was broken again, that that was the result of the defendant's unskilful handling of the case, and that the defendant did not use ordinary care and skill in his subsequent treatment The plaintiff testified

> The nurse went to take me out of the bed, and my limb broke over It broke so quickly I never knew how it broke I don't suppose the nurse knew how it broke I can't say whether the nurse supporting me twisted me or how it is, I just didn't know it was done so quickly

That was all the evidence there was as to how the break occurred eight weeks after the first injury, and there was no evidence that any directions which the defendant gave at that time were not the usual or proper instructions The plaintiff did not complain of anything that was done to his leg before the second break occurred There was an absolute want of evidence that the defendant did anything that he should not have done or omitted anything that should have been done The evidence only showed that the plaintiff was left in a very deplorable condition, but it also appeared that before he was injured he had varicocele veins and was over 50 years of age and that he suffered an injury that not infrequently produces in men over 50 years of age the result that followed The well settled rule in such cases is thus stated

> The law accords the medical practitioner the presumption that he has done his duty, and, in a suit for injuries caused by alleged malpractice, the burden is on the plaintiff to prove the want of reasonable and ordinary care or skill However, it is not necessary in an action against a physician or surgeon for unskilfulness or negligence to prove gross culpability on his part, proof of any failure to exercise proper care or any neglect in the discharge of the duty assumed is sufficient Further the burden is

on the complaining patient to prove that the injury complained of resulted from such want of care or skill A bare possibility of such result is not sufficient The burden of proof is not shifted by showing that an unsuccessful result has attended the treatment of the patient by the physician Nor does the unsuccessful result of the case shift from the plaintiff to the defendant the burden of going forward —21 R C L 406

Where the evidence is as consistent with the absence as with the existence of negligence, the case should not be left to the jury —30 Cyc 1588

What should be the rule when it is shown that the result obtained is not the result that may reasonably be expected where ordinary care and skill are used was not presented by the record and was not decided For there was nothing in the evidence showing that the condition in which the patient was left was other than might reasonably be expected, although proper care and skill were used The gist of the action was negligence, and negligence is not shown where only the result appears and this result may as reasonably be the result of other causes as of the want of proper care and skill To hold otherwise would be to place on the defendant the burden of showing the absence of negligence, when the plaintiff had not shown facts sufficient to show negligence The court therefore properly, under the evidence, instructed the jury peremptorily to find for the defendant, and judgment for the defendant is affirmed

Not Liable for Death After Injection of Procaine Hydrochloride

(Bishop v Shurly (Mich), 211 N W R 75)

The Supreme Court of Michigan, in affirming a judgment for the defendant, says that the plaintiff arranged with the defendant at his hospital for the removal of the tonsils of her son aged 19 years When the young man went to the hospital, an assistant to the defendant, instructed by the defendant to administer the anesthetic, gave a local injection of procaine hydrochloride consisting of 2 drachms of the solution of about 0 5 per cent in strength, after which the patient collapsed, and died in less than an hour The plaintiff contended that the contract she had made with the defendant provided that a general, and not a local, anesthetic should be used, and that the contract was breached by the defendant, wherefore, as administratrix of her son's estate, she brought this action to recover the damages the estate sustained by reason of his suffering and death The burden was on the plaintiff to satisfy the jury that her son died from the effects of the injection As the claim was set forth, the burden was also on the plaintiff to prove that cocaine had been administered

The assistant physician was permitted to testify, over the plaintiff's objection, that as the young man was entering the operating room a lady was passing out, that the young man asked what operation had been performed on her, and, on being informed that her tonsils had been removed, asked what anesthetic she had taken, and, when informed that it was a local one, asked why he could not have the same When told that he could, he inquired as to the manner in which it would be administered, which was explained to him, after which he said that he would take the local anesthetic and got into the operating chair used for that purpose When the plaintiff had elicited from the assistant physician facts which showed that a local anesthetic had been used, that the patient soon afterward collapsed, the efforts made to revive him, and that his death occurred in about fifty minutes, the court feels constrained to hold that the defendant was entitled to have the physician fully explain what occurred in the operating room after the patient had been brought there, prepared for the administration of ether That a change in the form of the anesthetic to be used was then made was apparent Why was it made?

The assistant physician was the representative of the defendant, charged by him with the duty to administer the anesthetic Any agreement made by him with the patient relative thereto would be as binding on the defendant as if he made it himself The patient was 19 years of age His father was dead He had a legal right to contract with the defendant for the performance of the surgical operation Such a service is within the meaning of the term "necessaries," for which infants may make binding contracts The contract made by the mother was made for and on behalf of her son It seems clear that he could at any time thereafter change or modify it as he might see fit to do Were this a proceeding wherein the defendant sought to enforce payment for the services rendered by him, under the claim of the plaintiff that she entered into the contract "as guardian for said minor, and for and on his behalf," as set forth in the declaration, it seems clear that his estate only would be liable to pay therefor

The sudden death of the patient was accounted for by the defendant by the presence in his person of the thymus gland In support of that theory the defendant was asked what he would have to say as to the probability of this thymic death having occurred had the general ether anesthetic been applied, instead of having procaine hydrochloride administered, and he answered that he believed the patient would have died just the same A similar question was put to another physician who answered it to the same effect Error was assigned on permitting these questions to be answered over the plaintiff's objection, but there was proof that any sudden shock might cause death in case the thymus gland was still persistent, and the court thinks there was no error in permitting these experts to express an opinion as to whether the use of ether as an anesthetic might produce such a shock There was, of course, no evidence that this gland was persistent in the body of the patient, as no necropsy was had because the mother would not consent to one, when the coroner urged it The death was sudden, and due to some unusual cause A surgeon of forty years' practice testified that there were no symptoms attending the patient's condition after the anesthetic was administered which would indicate or lead him to suspect that this was a death due to the administration of cocaine The court thinks the evidence was admissible in its bearing on the cause of death, and that there was testimony to support the verdict rendered for the defendant

Dying Declarations Confined to Homicide Cases

(Clark v State (Neb), 211 N W R 16)

The Supreme Court of Nebraska, in holding that it was error to permit the introduction of a dying declaration in a trial for sodomy, says that at the early common law dying declarations were admissible in all cases, civil or criminal Later a distinction was evolved and such declarations were received only in homicide cases This has been the general rule in this country for more than a hundred years It has been so long recognized as a rule of evidence that a court may well pause before overthrowing it There is an extensive discussion and a masterful criticism of this rule in 3 Wigmore, Evidence (ed 2), section 1436 The learned author indicts it as a heresy, but concludes the discussion by saying that it should be wholly abolished by legislation The rule has been so generally accepted and its overthrow might lead to such confusion that this court is constrained to adhere to it, and leave the lawmaking body to determine whether or not it shall be revoked What this court now holds is that dying declarations are admissible only in cases of homicide, and then only where the death of the declarant is the subject of the charge.

Effect of Ingestion of Zinc.—Drinker et al have never observed any significant clinical symptom nor obtained any significant laboratory evidence of harm resulting from the daily ingestion of zinc oxide over long periods of time With the exception of fibrous change in the pancreases of three cats subjected to doses of zinc greatly in excess of any possible human exposure, histologic examination following autopsy has not shown any injury in the organs of experimental cats and dogs attributable to zinc Studies on zinc excretion in zinc fed animals indicate that a small fraction of absorbed zinc leaves the body in the urine, but that the main bulk of it is excreted into the alimentary tract—some of it directly, some of it by the liver into the bile, and possibly some of it by the pancreas—and ultimately leaves the body in the feces The amount of zinc in the urine of zinc fed animals is markedly increased over the normal, though the total amount of zinc in the urine is only a small fraction of the total excreted It is worthy of note that animals excreted abnormal amounts of zinc through the kidneys for months without any histologic evidence of kidney injury A possible connection is suggested between the zinc content and the functional activity of the suprarenals and of the sex glands

Effect of Zinc on Growth.—Thompson et al found that the daily feeding of organic zinc salt solutions (acetate, citrate and malate) or of zinc oxide suspensions in doses of from 2 to 38 mg of zinc to albino rats, not only for many weeks previous to mating, but during pregnancy and lactation as well, did not have any significant effect on the health of the parents, on fertility, or on the health and early growth of the offspring The offspring of zinc fed parents, weaned at 23 days of age and themselves put on daily doses of zinc, grow at a normal rate and to a normal adult size

Effect of Sodium Chloride on Urinary Output.—The effect on the urinary output of water, chloride, inorganic phosphate, urea and ammonia of varying the sodium chloride and acid content of 500 cc of ingested water was determined by White The output of water in the first four hours following the drinking is diminished by increasing the salt content up to 0 9 per cent The output of urea and ammonia is independent of the salt content of the ingested water, the output of phosphate falls off as the chloride content rises from 0 to 0 6 per cent, and then rises with 0 9 per cent of sodium chloride The chloride output is in general independent of the chloride intake The output of water, phosphate and ammonia is increased by taking acid, the output of chloride and urea is unaffected by the acid

Nature of Autacoids of Posterior Lobe of Pituitary.—The "unitarian" theory of the autacoids of the posterior lobe put forward by Abel and his collaborators is criticized by Draper on the basis of the published results of these authors The pressor and oxytocic activities are shown to have a widely differing distribution during normal butyl alcohol extraction The results of Dudley and of Schlapp are thus confirmed The renal activity is shown to follow closely the pressor activity during normal butyl alcohol extraction The separation by extraction of the oxytocic activity from the renal and pressor activities is explained by assuming that the autacoid responsible for the oxytocic activity is chemically separate from that responsible for the pressor and renal activities The data obtained do not warrant a conclusion as to whether the pressor and renal activities are due to one or more than one substance A method of assaying the renal activity of posterior lobe extracts is described

Action of Anterior Lobe of Pituitary.—Johns et al assert that extracts of the anterior lobe of the pituitary body of the ox, when injected into healthy adult dogs, cause hyperglycemia, polyuria and glycosuria Extracts of the anterior lobe of the pituitary body of the ox produce polyuria and glycosuria but not hyperglycemia, polyuria and glycosuria Extracts of the anterior lobe of the pituitary body of the ox produce polyuria and glycosuria but not hyperglycemia in dogs which previously have been treated with the extracts The hyperglycemia is probably due to increased glycogenolysis in the liver The threshold value of the kidney for glucose is lowered as a result of the administration of the extracts The action of the extracts on blood pressure and uterine strips is not similar to the action of pituitary extract Extracts of liver and muscle made by the same process as the extracts of the anterior lobe of the pituitary failed to give similar results when administered to healthy adult dogs

Effect of Lactic Acid and Urea on Vessels—Perfusion experiments made by Kurtz and Leake in frogs indicate that small amounts of urea as well as lactic acid will cause vascular dilatation when the blood vessels are contricted by buffered Ringer's solution with a p_H above 7 3 or below 7 0 The effect is more striking in the alkaline range

Induced Precocious Sexual Maturity.—Precocious sexual maturity was induced by Smith by making daily homoplastic transplants of the pituitary from the adult, given intramuscularly Maturity occurred as early as the weaning date (22 days of age), thus transcending all normal variability Animals which are only 14 days of age when treatment is begun mature sexually in from eight to ten days, when the treatment is begun at the weaning date, they mature in five or six days The opposite response of the sex apparatus results from pituitary ablation before sexual maturity, the complete establishment of the vaginal canal being delayed and the genital system remaining undeveloped The anterior pituitary component of the transplant only is essential for the induction of premature sexual maturity, the posterior lobe of the pituitary neither hindering nor aiding in the response No stimulus to the development of the uterus or vagina or the immature ovariectomized rat is given by these transplants. The invariable and rapid maturity which is induced by daily pituitary transplants speaks against the view of those who maintain that hypophysectomy does not interfere with sexual development or function, and indicates an important hypophyseal-gonadal interrelationship.

Effect of Carbon Monoxide on Metabolism.—Walters says that carbon monoxide depresses the rate of metabolism, the degree of depression varying directly with the degree of saturation. There is a lowering of body temperature that corresponds closely with the slowing of the metabolic rate. The breathing of carbon monoxide concentrations of from 0.02 to 0.05 per cent for short periods (from one to two hours) has little, if any, effect on the rate of metabolism of the rat, but for long periods (from four to six hours) it depresses the rate in individual cases. Concentrations above 0.05 per cent have marked effects in depressing the rate, even for short periods of exposure. There is a correlation between the fall in the metabolic rate and the symptoms of carbon monoxide poisoning.

Effects of Anemia and Hemorrhage on Cardiac Output.—The effects of anemia and hemorrhage on the cardiac output of intact dogs have been studied by Blalock and Harrison by the Fick method. Diminution of the hemoglobin content of the blood is associated with an increased cardiac output. Progressive hemorrhage leading to decreased blood volume does not cause a marked change in cardiac output until the animal approaches a state of shock, when the cardiac output rapidly decreases. When blood volume is maintained by saline infusion, progressive hemorrhage is associated with an increased cardiac output, which diminishes as shock sets in. These effects occur in animals narcotized with morphine, and in trained unnarcotized animals. The time element is of considerable importance. The more rapidly a given degree of anemia is produced, the more is the output of the heart increased. It is suggested that capillary oxygen pressure may be an important factor in the regulation of the output of the heart.

Effect of Anoxemia on Cardiac Output.—Anoxemia has been produced by Harrison and Blalock by rebreathing, the carbon dioxide being absorbed. Anoxemia of a severe degree (greater than 30 per cent unsaturated) causes slight increase in the pulse rate, increased minute ventilation, diminished oxygen consumption, an uncompensated acid deficit and an increase of from 5 to 500 per cent in the minute cardiac output. These observations support the hypothesis that capillary oxygen pressure is an important factor in the regulation of the circulatory minute volume.

Susceptibility to Tetanus Following Suprarenalectomy.—The susceptibility of albino rats to tetanus toxin after suprarenalectomy was investigated by Rogoff and Ecker. They believe that there is no foundation for the statement found in the literature that partial or complete suprarenalectomy results in an increased susceptibility to tetanus toxin.

Effect of Excessive Amounts of Water.—From the experiments made by Greene and Rowntree, it seems evident that in dogs the forced administration of excessive amounts of water produced demonstrable changes in the volume and composition of the blood. This dilution is shown by a reduction in the hemoglobin and serum proteins, as well as by an increase in the plasma volume. The electrolytes in the serum are likewise reduced, but the concentration of chlorides and sodium decreases to a greater extent than would be expected from the degree of dilution. The behavior of the nonelectrolytes, urea and sugar is apparently determined by factors other than the dilution, and so is partially independent of the water administered.

Dermatophytosis. C. M. Williams, New York.—p. 451.
*Status of Nonspecific Treatment in Dermatology. P. A. O'Leary, Rochester, Minn.—p. 470.

Fungus Diseases of Skin.—White presents the results of a study of 1,013 cases of epidermophytosis. The infection attacks persons of all ages, and has no geographic locale, no epidemicity. A tight-fitting woolen bathing suit, woolen tights, woolen socks, woolen gloves, baseballs, gloves, reins, handles of golf clubs, trusses, straps of wrist watches and shoes worn without stockings, suspensory bandages, athletic clothes and silk underwear are all sources of the infection. Less than 6 per cent of the cases were familial. The local treatment of this disease has proved most disappointing. The best results have been obtained from the use of a 2 per cent aqueous solution of mercurochrome.

Status of Nonspecific Therapy.—O'Leary has not seen any benefit whatever from the use of nonspecific measures in cases of eczema in practically all of its manifestations, in the chronic form of discoid lupus erythematosus, or in allergic dermatitis.

Carcinoma of Male Breast.—Wainwright made a study of the literature, hospital records and personal communications bearing on this subject and, as the result, analyzed 418 cases.

Rhabdomyosarcoma of Vulvar Orifice in Children.—At the age of 14 months, Lockwood's patient began to pass polypoid masses, the size and shape of muscat grapes, which the mother discovered on the diaper. The child was taken to the family physician who found a large mass of polypi, similar to nasal polypi, springing from the posterior vaginal wall. These were removed but soon recurred. The child suffered severe hemorrhage, causing profound anemia. Lockwood saw her two months later when he removed a pedunculated tumor mass, the size of a small orange, from the posterior raphe of the vagina. Over its upper surface, many polypoid tumors resembling a cluster of grapes were found. The child rapidly regained her health and normal weight. She remained well more than nine months—when she again passed two or three small polypi. There was no return of the tumor at the original site, but the abdomen began to fill, and the patient gradually became emaciated. She died at the end of three months of toxemia and exhaustion.

Treatment of Carbuncles by Blood Injection.—Twelve patients who had carbuncles were treated by Carp with circuminjection of autogenous blood without other operative procedure. The blood was withdrawn from the median basilic vein. The infection did not spread, except in one case. There was quick relief from the pain and constitutional symptoms. Reaction was not observed after the injection. Most of the slough liquefied. The injected blood seemed to remain in the tissues, with gradual modification, for from several days to two weeks, as evidenced by induration in the injected area, ecchymosis or both. All the patients showed a minimal scar at the time of discharge from the hospital.

Cerebral Concussion.—Miller asserts that concussion is immediate in onset, and tends to spontaneous recovery without sequelae. The most important symptom of concussion is complete unconsciousness with or without medullary symptoms. Concussion appears to be due to direct mechanical action on the cells, which causes a disturbance of cell equilibrium and temporary loss of function. The medullary effects are those of stimulation or paralysis of the respiratory, vagus and vasomotor centers. The respiratory center is the first to be paralyzed. As this is usually a temporary paralysis, artificial respiration may save life. Death from concussion is immediate and is due to respiratory paralysis with consequent asphyxia.

Effect of Alkali on Cardiac Output During Anesthesia.—The experiments made by Blalock indicate that the routine administration of alkali before operations does not seem advisable.

*Uterine Index of Development: Hysterometer. S. R. Meaker, Boston.—p. 615.

Effects of Tonsillectomy on Rheumatic Fever.—Robey and Freedman believe that complete enucleation of the tonsils offers the best preventive of rheumatic fever, and therefore of rheumatic heart disease. A history of repeated sore throats is of more importance than tonsils which by appearance suggest disease. Repeated sore throats, even with tonsils of normal appearance, call for tonsillectomy. If the tonsils are diseased in appearance, they should be enucleated even in the absence of sore throats. Tonsillectomy is a major operation, and should be performed only by persons duly qualified by training and experience. Incomplete tonsillectomies leave the patient in as dangerous a situation as before, and throw discredit on the value of tonsillectomy as a preventive. Tonsillar remains are often as formidable as the original tonsil.

Amputation for Prosthesis.—The points of election in amputating and the postoperative care are outlined by Jepson. Attention is called to the fact that, in amputating, the main consideration is not to save all the tissue possible but to provide a stump to which a useful prosthetic appliance can be readily attached. The general types of prosthetic appliance and their advantages are briefly described. The desirability of an early return of the amputated member to function is emphasized.

Uterine Index of Development.—Meaker asserts that the ratio of uterine body to cervix may, in effect, be regarded as an index of the degree of development of the organ. In the truly infantile state the ratio of the length of the supercervical uterine cavity to the length of the cervical canal is 1:2, while in the fully developed adult organ it is 2:1. Turning these ratios into fractional form, the infantile condition would be expressed as ½, or 0.5, and the adult normal as ²⁄₁ or 2., while the various intermediate grades of hypoplasia would fall between those figures. Since it is convenient to have perfection represented by unity, the whole series of figures may be divided by 2. Thus a uterine index is created, ranging from 0.25 to 1, and expressing every degree of development from complete infantilism to the adult normal. This uterine index in any given case is calculated according to the formula $\frac{1}{2}\left(\frac{u-c}{c}\right)$, u being the length of the entire uterocervical cavity and c the length of the cervical canal. Information of this sort is of the highest importance, for marked developmental arrests in the uterus are almost certain to be associated with corresponding imperfections in ovarian development, and hence with defective ovulation and sterility. For the accurate taking of uterine measurements, Meaker has devised an instrument to which the name hysterometer has been given.

Nontuberculous Lung Diseases Simulating Pulmonary Tuberculosis.—Winner discourses on some pulmonary conditions closely resembling pulmonary tuberculosis, and at times admitted to the sanatorium with that diagnosis. Of twenty-two cases of lung abscess, the causative factor was tonsillectomy in 32 per cent; pulmonary infection in 23 per cent; appendectomy in 9 per cent, and measles in 4 per cent. There were three cases of carcinoma of the lung. Among 9,942 discharged cases were found 293 cases of pulmonary tuberculosis with positive Wassermann reactions; two cases were considered as syphilis of the lung.

Prematurely Born Infants.—Multiple pregnancy was the most common single cause of premature labor in the 266 cases analyzed by Hess and Chamberlain. Excluding fifty-four babies that died in the first twenty-four hours, 66.9 per cent survived. Immaturity, refrigeration and neglect were the common causes of death in those dying in the first twenty-four hours. Necropsies were performed in seventy-nine cases. Bronchopneumonia with and without atelectasis was present in a large number of the fatal cases. Intracranial hemorrhage was found in thirty-one of the sixty-nine cases in which the skull was opened. Several other cases showed positive evidence of intracranial hemorrhage which, however, was not proved by necropsy.

Pernicious Anemia in Negro.—Of 256 patients with pernicious anemia, forming the basis of Traut's paper, eight were colored. Whether these were mulattoes or full-blooded negroes was not determined. The age of these patients ranged from 25 to 62 years. Three were males; five were females. The average duration of symptoms previous to admission was from two weeks to seven years. Five of the patients had had symptoms for more than one year; the remaining three for less than two months. The disease could be classed as severe in all the cases. Five of the patients died. The remaining three were discharged unimproved after long periods. The diagnosis was substantiated by necropsy in three instances. Of six patients with the diagnosis of aplastic anemia, one was a negro. The diagnosis was confirmed at necropsy.

Action of Ultraviolet Rays on Cholesterol.—The action of ultraviolet rays on the ethers and esters of cholesterol was studied by Bills and McDonald Among the esters of cholesterol, the acetate, isobutyrate and benzoate are readily converted into antirachitic modifications by the action of ultraviolet rays Cholesteryl cinnamate is not appreciably activated, but there is evidence that the molecule is altered, the alteration taking place at the double bond of the cinnamate radical, instead of in the cholesteryl radical The antirachitic rays probably induce molecular changes in ordinary cinnamic acid, but they do not render cinnamic acid antirachitic. In the activation of cholesterol esters, the ester molecule as such, and not cholesterol liberated therefrom, is the substance activated Fourteen cholesterol ethers of widely divergent structure failed to become antirachitic on irradiation Whether they underwent molecular alteration of any kind has not been determined In the activation of sterols, both the double bond and the alcohol group are involved. The former must be intact, the latter may be replaced by certain acid radicals

Preparation of Crystalline Guanine Nucleotide.—A method is described by Buell and Perkins for the easy and certain preparation of crystalline guanine nucleotide from yeast nucleic acid

Determination of Carbon Monoxide in Blood—A technic is described by Van Slyke and Robscheit-Robbins for the quantitative gasometric determination of small amounts of carbon monoxide in blood

Preparation of Insulin.—A method for the preparation of insulin is described by Blatherwick et al This method gives a good product with comparatively less effort than is required by other procedures Various methods of purifying crude insulin are discussed

Sympectothion in Blood.—For the substance previously isolated by them, and then termed substance X, Hunter and Eagles now suggest the name sympectothion, as it contains "firmly bound" sulphur The characteristic phosphotungstate of sympectothion has been isolated from human blood The relation to sympectothion of a substance recently isolated by Benedict, Newton and Behre is discussed

Glutathione Normal Constituent of Blood.—Evidence is given by Hunter and Eagles that glutathione is commonl present in human and animal blood corpuscles to the extent of 100 mg per hundred cubic centimeters There is more glutathione in mammalian corpuscles than in mammalian muscle The presence of glutathione in blood is discussed from the point of view of blood analysis and from a physiologic standpoint

Preparation of Glutathione.—Glutathione has been prepared by Hunter and Eagles from yeast, blood and liver, and the products from the different sources appear to be chemically identical when allowance is made for the presence of free cystine in the liver product The preparations, however, are at variance, especially as to the content of total nitrogen, aminonitrogen, and sulphur with the theoretic requirements of diglutaminylcystine These results suggest that reduced glutathione is not a simple dipeptide of cystine and glutamic acid, although those two amino-acids are present

Cystine in Liver—Pure cystine has been isolated from liver by Hunter and Eagles It is suggested that the free cystine in liver may be of importance in the formation of taurocholic acid, and that one of the manifestations of cystinuria may lie in a hepatic failure to metabolize the free cystine of liver

Estimation of Cystine and Glutathione.—A colorimetric method is described by Hunter and Eagles for the accura estimation of cystine and glutathione in simple solutions. It is shown that 4.64 parts of pure cystine yield the same amount of color as ten parts of glutathione. The amount of cystine in hydrolyzed glutathione has also been measured.

Growth Experiments with Fat Diets.—Levine and Smith assert that growth at a normal rate, from 30 to 180 Gm. in body weight, can be induced in rats on a high fat ration practically devoid of preformed carbohydrate and containing 86 per cent of the total calories in the form of fat, provided the protein and salt requirements of the animal are fulfilled. The livers of some of the rats that had been on this high fat ration for a period of eighty-three days, when examined microscopically, did not contain fat droplets. It appears that rats receiving a maximum of calories in the diet in the form of fat can grow as efficiently, measured by energy cost, as when a mixture of calories derived from both fat and carbohydrate is present in the ration.

Hyperglycemia and Hypoglycemia Caused by Witte's Peptone.—Experiments made by Menten and Manning show that different samples of Witte's peptone, when injected intravenously in rabbits, vary widely in the manner in which they modify glycemia. The change in blood sugar ranges from a lack of appreciable alteration through varying degrees of hyperglycemia to a fatal hypoglycemia.

Nutritional Anemia on Whole Milk Diet.—Hart et al. show that the deficiency in milk leading to nutritional anemia is of inorganic character rather than of organic nature.

Nature of Thiosine.—Thiosine has been identified by Newton, Benedict and Dakin as ergothioneine (betaine thiolhistidine). Thus it would seem that the name thiosine should be abandoned. Yet the term ergothioneine seems hardly appropriate as applied to a product which is certainly widely distributed among mammals. The authors suggest dropping the prefix "ergo" and using the term "thioneine." The large amount of the compound present in corpuscles indicates that it is of very definite importance in the organism. Observations up to the present time indicate that thioneine is present in human blood in amounts of from 10 to 25 mg. per hundred cubic centimeters of blood.

Action of Blood on Sulphides.—Analysis made by Denis and Reed of the blood of dogs that had received sodium sulphide by intravenous injection, or by injection into the intestine, sometimes showed a rise in the inorganic sulphate but no increase in the neutral sulphur fraction. These increased values were noted particularly in the case of animals in which the kidneys had been tied off. The results are believed to give support to the theory that hydrogen sulphide is detoxicated by oxidation to sulphuric acid.

Van den Bergh Reaction for Serum Bilirubin.—The van den Bergh reaction is a means of qualitative (direct reaction) and quantitative (indirect reaction) study of serum bilirubin. The presence of bile salts in the serum of obstructive jaundice probably explains the prompt direct reaction of the bilirubin in this type, and is the essential difference in serums of obstructive and hemolytic jaundice. The term biphasic was used to describe a direct reaction which began before thirty seconds had elapsed, following the addition of the diazo reagent, and increased in intensity for some time after the thirty second limit. Hall feels that this designation (biphasic) is misleading and should be dropped, for no serums, even those most heavily jaundiced (obstructive), reach their maximum color until long after thirty seconds have elapsed. He classes the direct reactions as follows: prompt or immediate, any reaction beginning in thirty seconds after the addition of the reagent to the serum; delayed, a reaction beginning slowly after thirty seconds and reaching its maximum very slowly, sometimes taking thirty minutes or longer; negative, those in which no color at all developed. In calculation of the dilution in the quantitative reaction, the quantity of supernatant alcoholic solution should be read and that figure used, as the bilirubin in the serum (1 cc.) is all present as azobilirubin in the alcohol. The aqueous cobalt sulphate standard is more desirable than the ether standard. It is more easily handled, is not subject to rapid evaporation and can be made up in quantity. Comparison with the ferric sulphocyanate-ether standard is recommended as a means of avoiding gravimetric errors, if a crystalline cobaltous sulphate is used. Addition of a small amount of concentrated sulphuric acid (from 0.5 cc. to 100 cc. of standard) does not change the color of the cobalt standard and helps preserve it. Serum bilirubin reactions do not appear to change on standing, if refrigerated.

Differential Stain for Leukocytes.—For diluting and staining fluids, Nicholson uses 6 per cent Giemsa's stain in 20 per cent acetone solution as the most satisfactory. The pure Giemsa's stain is kept in one bottle and 20 per cent acetone in distilled water in another. Before making a count, 0.6 cc. of Giemsa's stain is added to 10 cc. of the 20 per cent acetone solution. A large drop of the diluting fluid is placed on a glass slide, and a small drop of blood is added by means of a platinum loop.

Toxicity of Tetra-Ethyl Lead.—The toxicity of tetra-ethyl lead has been determined by Kehoe for rabbits by the various methods of administration. Comparison of the toxicity of tetra-ethyl lead with an inorganic lead salt indicates that its toxicity is a function of its lead content. An explanation of the delayed effect of tetra-ethyl lead, as compared with salts of lead, is offered. It is suggested that tetra-ethyl lead owes its toxicity to a decomposition reaction which produces water soluble compounds of lead that are capable of coagulating proteins.

Chloride Content of Canned Sauerkraut.—Analyses made by Stark of the salt content of canned sauerkraut gave values as follows for total chlorides, expressed as sodium chloride ($NaCl$): 1. For juice (eleven cans, including eight brands), in grams per hundred cubic centimeters: average, 1.881; maximum, 2.228; minimum, 1.502; in grams per hundred grams (per cent): average, 1.830; maximum, 2.167; minimum, 1.469. 2. For solid kraut (seven samplings from five cans, including four brands), in grams per hundred grams (per cent): average, 1.736; maximum, 1.947; minimum, 1.605.

Complement Fixation Test for Tuberculosis.—Of twenty-seven patients with advanced tuberculosis, expectorating bacilli, on whom Ogawa performed this test, twenty-six yielded positive reactions with the Kolmer antigen. The one negative case was so far advanced that death occurred seventeen days after the test was made. The serums from eleven cases of the same series were tested with the Besredka antigen, and in six samples a positive reaction was obtained. Of 111 patients regarded as tuberculous but without expectoration of bacilli, ninety-nine reacted positively with the Kolmer antigen; twenty-two of these were tested with the Besredka antigen, and ten reacted positively. Of the pleural fluids from fifty cases of tuberculous pleuritis tested with the Kolmer antigen, thirty-eight yielded positive reactions. Of sixty-eight fluids tested with the Besredka antigen, fifteen reacted positively. In a group of seventy-nine patients with syphilis and positive Wassermann reactions, the Kolmer and Besredka antigens yielded from 20 to 66 per cent positive reactions; some of these persons were probably tuberculous as well.

New Mask for Basal Metabolism Determinations.—Rowe has modified the construction of Kops' war gas mask so far as to arrest complementary leakage from within.

Polycythemia Vera Treated with Phenylhydrazine Hydrochloride.—Altnow and Carey report a case of polycythemia vera, in which they administered a total of 2.6 Gm. phenylhydrazine hydrochloride in 0.1 Gm. doses over a period of ten days, and effected a complete amelioration of the symptoms of the disease. The drug produced a marked reduction of the absolute lymphoid count, either by destruction of these cells or by a depressive effect on the reticulo-endothelial structures, inhibiting their formation.

Blood Culture Technic.—Manheims and McGrath assert that the addition of 2 per cent sterile sodium citrate solution, in sufficient quantity to prevent the coagulation of blood, does not inhibit the growth of pathogenic organisms in this blood, and provides a simple and satisfactory method of taking routine blood cultures.

Quantitative Blood Sugar Estimation.—Evidence is given by Byrd that the Folin-Wu micromethod, using 0.1 cc. of blood, is just as reliable as any method now in use, irrespective of the quantity of blood necessary for different technics, and regardless of the sugar content of the specimens analyzed. It can be applied in any case in which the need of a quantitative blood sugar estimation is indicated, including infants, small children and obese individuals. Its advantages are obvious.

Hereditary Congenital Familial Hemorrhagic Nephritis—The cases of hemorrhagic nephritis which have come to Alport's notice belong to a later generation of the series studied by Leonard Guthrie and Hurst All the children of three generations of one family suffer from hematuria or nephritis, associated with deafness The deafness, which has not been stressed in the literature on the subject, is one of the most distressing features of this extraordinary disease This nerve deafness is apparently of the type of defective hearing It occurs not only in the individuals who have nephritis or hematuria, but also in those who are otherwise perfectly healthy Alport points out that hereditary familial or congenital nephritis is a definite entity, and the kidneys in these patients are more susceptible to injury by the toxin of an unknown organism than is the case in the normal person The organism probably belongs to the streptococcal group In the first case investigated by Alport, the coagulation time of the blood was delayed, intravenous injections of 1 grain (0 065 Gm) of calcium chloride reduced the coagulation time and caused a reduction in the amount of blood and albumin in the urine Calcium lactate given by the mouth is useless, as it is not absorbed by the intestines Cultures of *Streptococcus viridans* found in the stools of this patient, and of his cousin, failed to produce the disease when introduced into the veins of a rabbit Cultures of the stools of another case, which showed both *S viridans* and hemolytic streptococci, caused changes in the urine and kidneys of a rabbit after intravenous injections The male members of a family tend to develop nephritis and deafness and do not, as a rule, survive The females have deafness and hematuria and live to old age Two of the cases are interesting evidence of the variations in the course of nephritis The kidneys of two members of the same family were attacked, apparently by the same organisms, at the same time, and under exactly the same conditions The elder brother contracted acute nephritis, which cleared up completely, the younger developed parenchymatous nephritis, passing into small white kidney and ending in death

Mortality of Acute Appendicitis—Hunter reviews a large number of cases of appendicitis, showing 1 8 per cent case mortality, excluding the general peritonitis cases, and 3 5 per cent for all cases, as evidence in favor of immediate operation in acute appendicitis

Ultraviolet Therapy of Asthma—Bryce gives the results of ultraviolet therapy in a typical case of spasmodic asthma and bronchitis of the most severe character, in a typical case of protein sensitization, and in a typical case of asthma alternating with eczema He reports that he has seen many cases of neuritis and lumbago cured by the use of ultraviolet rays The most useful function of ultraviolet rays is their power to increase the absorption of calcium and phosphorus This leads not only to the better nutrition of the bones and nervous system, but also to the alleviation of spasm and the induction of a calmative effect on the nervous system Nor must it be forgotten that there is an increase of iron in the blood and a decided rise of hemoglobin in the erythrocytes, diminishing the risk of dyspnea and asphyxia, so potent a factor in asthmatic conditions Finally, the internal secretions of thyroid and suprarenals are increased, and both are valuable in the treatment of asthma and allied conditions

Estimating Cardiac Output—In the method described by Harris, the venous pressure is measured by inserting a needle, preferably in the cephalic vein of the arm A given number of heart beats are admitted Then the pressure is taken again, and from the increased venous pressure the output per beat, or, if desired, per minute is calculated The principle underlying this method is the determination of the single output by variation of the venous pressure

Fatal Acute Pulmonary Edema—The point worthy of interest in Posel's case was that the rhythm of the heart was regular throughout the attack The cause of the sudden onset of the alarming and fatal symptoms was not determined

Extensive Necrosis in Chickenpox—In the case reported by Dykes, a child, aged 2 years and 9 months, contracted chickenpox from her sister, aged 8 There was a slightly reddened, tender patch over the lower part of the right shoulder-blade, alongside a vesicle There were not more than twenty vesicles in all on the body and head The heart and respiratory sounds were normal The following day the temperature had fallen a degree, but the general condition had not improved The area of redness over the right shoulder blade had increased, and there was a wide margin of tenderness beyond During the succeeding forty-eight hours, the condition grew worse On the fourth day a small necrosed patch, rather smaller than a shilling, was then present at the original site of the inflammation, and below this the skin was discolored Tenderness and muscular spasm extended to the vertebral column posteriorly and to the middle line of the chest and abdomen anteriorly There was tympanites and constipation The necrosed patch increased in size daily There was no suppuration, but the body became dusky and mottled By the morning of the sixth day the patch, roughly oval in outline, measured about 1½ by 3 inches (4 by 7 5 cm), and was beginning to separate at its upper margin The child died the morning of the seventh day

*Tea in Treatment of Burns J K Shen —p 150
Leprosy L S Huizenga —p 153
Anesthesia by Ether R M Gibson —p 157

Esophageal Atresia—The esophageal atresia in the case reported by Sheelshear and Anderson occurred at the level of the upper border of the arch of the aorta An arterial anomaly was associated with this The arch of the aorta first gave rise to the two common carotid arteries, which sprang from a short common trunk, in close proximity to this trunk the left subclavian artery arose, and finally the abdominal right subclavian artery, from the descending aorta

Contagion of Poliencephalitis.—The possibility of the brain being involved in patients suffering from common "colds' is illustrated by four cases, cited by Woods, in which a respiratory infection, apparently communicated from a woman to three of her nurses, resulted in a paralysis of the motor nuclei of the whole brain stem in each patient, and a mild involvement of the motor nuclei of the spinal cord The picture presented by these four cases was that of a throat infection accompanied by fever, followed within two weeks by paralysis, first of the eye muscle centers and then, seriatim, of those of the chewing muscles, the facial, palatal, tongue and swallowing muscles The nuclear involvement spread to the motor centers of the neck, including the phrenic, and, to a lesser extent, to the motor centers of the whole spinal cord

Mortality of Eclampsia—In the series of 110 cases analyzed by Whitmore there were eighteen deaths—forty cases treated conservatively, with four deaths, and seventy cases treated radically, with fourteen deaths.

Ascaris Causes Abdominal Disturbances.—*Ascaris lumbricoides* is one of the most common parasites found in Korea In a series of 5,000 examinations reported on by Ludlow, *Ascaris* was present in 53 2 per cent In a second series of 4,000 examinations, it was present in 44 2 per cent Of 454 surgical patients, 207 were infested with *Ascaris* Three cases of appendicitis, two of abdominal wall abscess with perforation at the umbilicus, all in children, and one case of *Ascaris* in a gallstone, have been observed The following conditions due to *Ascaris* are reported in detail (*a*) intestinal obstruction, gangrene of a portion of the ileum, (*b*) intraperitoneal abscess, postoperative appearance of *Ascaris* through the drainage incision, (*c*) general peritonitis from perforation of the ileum

Tea in Treatment of Burns—Tannic acid has been used in the treatment of burns rather extensively in Shen's clinic, and its efficacy has been amply demonstrated It occurred to him, however, that as the principal active ingredient of tea is tannic acid, it might be possible also to use strong infusions of tea for the treatment of burns It further occurred to him that as tea is the beverage in China, as well as in the other Oriental countries, a common therapeutic measure for burns might be developed which can be readily used in any household The fifteen minute, 8 per cent, infusion of average green or red (black) tea is considered as most suitable for the treatment of burns The infusion can be sterilized by boiling for three minutes Good results are reported.

*Red Blood Cell Sedimentation Test in Mental Diseases A Pijper and E D Russell —p 74
Stimulating the Phagocytes H Bodkin —p 83

Sedimentation Test in Mental Diseases—Pijper and Russell have applied the sedimentation test in 625 cases distributed among seven mental disorders dementia praecox, 361 cases, manic depressive psychosis, thirty, general paralysis, twenty-eight, alcoholic psychosis, twenty-four, epilepsy, ninety-five, defective mental development, fifty-two, and senile psychosis, thirty-five cases The test is not specific for any disease The small number of positive reactions in the early stages of dementia praecox makes the test not very helpful for the diagnosis of early dementia praecox Untreated cases of general paralysis give a positive sedimentation reaction, and treated cases (malaria or tryparsamide) that show a good remission give a negative sedimentation reaction In alcoholic psychoses a positive result is obtained in 75 per cent of cases Improvement sometimes seems to retard sedimentation Epileptic patients give a positive reaction only in congenital long standing cases with considerable mental deterioration In cases of defective mental development and senile psychoses, a fair number of positive reactions are obtained

Psoriasis Pustulosa A Fukai —p. 221.

Osteitis Deformans Frambesica.—Matsunaga reports on twenty-four cases of deformity of the forearm and leg. The radius was thickened, especially on the radial side, increasing in degree toward the wrist It was also bowed The ulna was likewise thickened, especially toward the ulnar side and the elbow It, too, was bowed. The tibia was thickened and bowed forward The fibula was slightly thickened The cause of these changes was an attack of frambesia, which, Matsunaga says, should be borne in mind in every case of osteitis deformans occurring in the tropics

Immunologic Relationship Between Syphilis and Frambesia—Matsumoto and his associates found that rabbits which have had syphilis but which have been cured by adequate arsphenamine treatment may be infected scrotally with frambesia with great ease, a characteristic lesion being produced, in which the spirochetes are to be found The immunity to syphilis and to frambesia acquired by an animal suffering from syphilis is quite different

Anemic Nevi with von Recklinghausen's Disease.—Shimomura's patient was aged 22 He presented typical symptoms of von Recklinghausen's disease and, in addition, multiple, irregularly shaped anemic nevi on the right side of the chest

Absorption of Dyestuffs by Stomach.—Kobayashi has studied the absorption of thirty-one dyestuffs by the stomach, which are excreted after being injected into the blood circulation from the liver and the kidneys, and he is convinced that sixteen are absorbed. Dyestuffs which have greater diffusibility than about 5.5 cm. in eight days in 0.5 per cent agar-agar-gel are absorbed by the stomach, and those of lesser diffusibility than 5 cm. are not. Furthermore, the more diffusible a dyestuff is, in general, the more of it is absorbed in a certain time.

*Specific Value of Dick Test in Determining Susceptibility to Scarlet Fever. T. Toyoda and J Moriwaki, Y. Futagi and M. Takeda—p 9.
*Relation Between Schultz Charlton Blanching Test and Dick Reaction in Scarlet Fever. T. Toyoda and J. Moriwaki and Y. Futagi—p 12.
Relation Between Dick Test and Schultz Carlton Phenomenon in Scarlet Fever Recidivation. J. Moriwaki, Y. Futagi, S. Hoshizaki and Y Tanaka—p 13
*Preventive Immunization Against Scarlet Fever in Dairen, South Manchuria. T. Toyoda and J. Moriwaki and M Takeda—p. 14
*Therapeutic Value of Antistreptococcus Toxin Serum in Scarlet Fever. T Toyoda and J. Moriwaki, Y. Futagi, S. Hoshizaki and Y Tanaka.—p 16

Active Principle of Opium When Smoked.—Nakajima and Kubota found that about 15 per cent of the alkaloids of smoked opium is dissipated in the smoke, and is not burned in the pipe. At least one of the chief active principles of opium smoke is morphine.

Water Absorption and Excretion by Epidermis.—Fukuchi concludes that the surface of the epidermis is able to absorb and discharge water rapidly, while the diffusion in its tissue is very slow. It is therefore probable that the content of water in the epidermis of a living subject is very different at its surface and beneath it. The former is extremely dry and the latter is very moist

Congenital Anomaly of Heart.—Ischii reports a case of cor biloculosis, with persistence of the truncus arteriosus communis.

Specific Value of Dick Test.—Toyoda et al. found that the Dick test, applied to 11,284 Japanese, was positive in 37.3 per cent, the highest figure being for children, aged 3 years, namely, 80.9 per cent

Dick Test to Determine Susceptibility.—Toyoda et al. conclude that natural immunity to scarlet fever has a close relation to the Dick toxin, and that the Dick test is a reliable means of determining the susceptibility or immunity to scarlet fever.

Relation Between Schultz-Charlton Test and Dick Reaction.—Toyoda et al. found a specific relation existing between the Schultz-Charlton phenomenon and the Dick test.

Preventive Immunization Against Scarlet Fever.—Toyoda et al. conclude that while preventive immunization against scarlet fever after the application of the Dick test may be a definite aid in preventing further severe attacks, it cannot be said to secure absolute immunity from the disease, at least not in South Manchuria.

Therapeutic Value of Antistreptococcic Serum and Antitoxin in Scarlet Fever.—Antistreptococcic and antitoxin serums have had a marked specific effect in the cases of scarlet fever treated by Toyoda and his associates. The mortality in serum treated cases was 24 per cent; in the nonserum treated cases it was 45.5 per cent.

*Myositis Ossificans Progressiva Multiplex: I. T. Ipponsugi—p. 343.
*Id · II. T. Ipponsugi—p 425
Id: III. T. Ipponsugi—p 461
*Pathology of Chronic Kidney Tuberculosis. M. Koike—p. 490.

Progressive Multiple Myositis Ossificans.—Study of a typical case of myositis ossificans multiplex progressiva has convinced Ipponsugi that the new bone formation takes place in the interstitial connective tissue of muscles or in the fascia of tendons but never in periosteum, this membrane, at most, being affected only secondarily The newly formed bone frequently is connected with skeletal bones by means of a plate of cartilage. Morphologically and functionally, this union is comparable to a pseudarthrosis.

Myositis Ossificans; Calcification Areas.—In this case, Ipponsugi found calcific masses in the kidneys, brain, mucous membrane of the colon, tracheal cartilage, walls of the spleen arteries and, in large amount, the pineal gland. Bone was not found in these structures

Pathology of Kidney Tuberculosis.—Koike examined 109 kidneys removed because they were the seat of chronic tuberculosis, usually of the caseous form (sixty-eight cases). These sixty-eight kidneys showed the most marked changes. The work of Wildbolz is confirmed.

Relation Between Venous Tension and Tension of Cerebrospinal Fluid.—In twelve healthy persons, Tzanck and Renault found that the venous tension was identical with that of the cerebrospinal fluid In diseases with a high venous tension. there was almost constantly a high tension of the cerebrospinal fluid. The balance between the two tensions is explained by the close anatomic connection of the subarachnoid space with the surrounding venous plexuses, hence, with the two venae cavae In hypertension of the cerebrospinal *fluid, the venous tension ought to be examined simultaneously* Failure of parallelism between the two tensions may [illegible] a valuable sign in diagnosis.

Pilocarpine as Adjuvant of Acridine in Treatment of Gonorrhea.—Jausion and Pecker's experience includes twenty-nine patients with gonorrhea A dose of 5 cc. of a solution containing 0.02 Gm of diamino-acridine chloromethylate and 0.001 Gm of pilocarpine nitrate per cubic centimeter was injected by the vein The injections were repeated at intervals of one day Discomfort from the injection did not last more than half a minute Usually, nine injections brought about recovery or great improvement The action of pilocarpine chlorhydrate proved to be analogous to that of pilocarpine nitrate.

Crossed Vaccination of Guinea-Pigs with Typhoidal Infection.—Dalsace and Gory injected a series of guinea-pigs with a virulent culture of typhoid or paratyphoid bacilli The animals developed a mild infection, inducing immunization. Another series of guinea-pigs were given typhoid and paratyphoid autolysates, and then tested with virulent typhoid bacilli. The immunity appeared to be more thorough than *in the first series In both instances the test inoculation* caused notable local *reaction, developing into an abscess.* This occurred when the inoculation was made by way of the skin or by that of the conjunctiva

Serum of Guinea-Pigs Immunized Against Typhoid.—Grasset and Gory inoculated guinea-pigs with typhoid or paratyphoid autolysates treated with formaldehyde and heat. The local reaction was insignificant; the general condition *remained* unchanged. *On the other* hand, injection of untreated autolysates in doses one-fortieth as large was fatal. Guinea-pigs immunized with treated autolysates were hyperimmunized with large doses of a virulent culture. The serum of these animals injected into fresh animals immunized the latter against the infection.

Mechanism of Hemolysis of Bacterial Origin.—Muller emphasizes the fact that cultivation of staphylococci on blood agar causes decoloration of the *medium.* Evidently, the coccus represents a hemolytic micro-organism which should properly be called hemodestroyer or hemophage. The destruction of the blood can be ascribed only partly to the action of the staphylococcus. A filtrable agent *may* be present in the human *blood, the hemolytic activity of which is conditioned by the presence* of the staphylococcus.

***Increase* of Insulin in the Blood of the Pancreatic Vein After Irritation of the Vagus.**—La Barre established anas*tomosis* between the pancreatic vein of a dog and the jugular vein of another dog. Then the peripheral end of the right vagus of the donor dog was exposed to an electric current. This was followed in the other dog by hypoglycemia, similar to that from administration of insulin. Furthermore, venous blood from the pancreas was *transfused into depancreatized* animals It caused *considerable reduction of the* experimental hyperglycemia. The antidiabetic action of the pancreatic blood appeared much stronger than that of the carotid blood The facts testify to a physiologic insulinemia.

Elective Permeability of Gelatin for Calcium Chloride.—Bigwood's researches showed that gelatin jelly hydrolyzes a neutral solution of calcium chloride, and increases notably the hydrogen ion concentration of the solution. This is due to the elective permeability of the gelatin for chlorine and calcium ions *The phenomenon occurs* without *the presence* of a dialyzer separating the protein medium from the aqueous solution.

Glucose Does Not Prevent Poisoning from Cyanogen Compounds.—In the experiments of Heymans and Soenen, guinea-pigs and rabbits treated with glucose did not resist inhalations of hydrocyanic acid longer than did nontreated animals. Resistance to the poisoning was increased in animals treated with sodium hyposulphite. This confirms the observations of *Lang* and Heymans.

***Transmission* of Action of Cardiac Nerves by the Medium of Fluid.**—*Rylant's* experiments were conducted on cats, rabbits and dogs. The isolated heart of an animal was irrigated with Locke's solution, and the liquid used in the perfusion was transferred to the isolated heart of another animal. Irritation of the vagal fibers in the first heart caused reduction in activity of the second heart. Irritation of *the sympathetic nerves* in the donor's heart increased the activity of the other heart. The vagal disturbances in the recipient heart *yielded* to atropine; the sympathetic disturbances, to ergotamine.

Influence of Certain Dyes on Permeability of Meningeal Vessels for Viruses.—Le Fèvre de Arric and Millet injected rabbits subcutaneously with various dyes, and then introduced herpes or rabies virus by the vein. It appeared that hexa*methyl violet,* methylene blue, neutral red, trypan blue and fluorescein *favor fixation of the virus in the nervous system.* This action on the part of the dyes *proved to be connected* with their retention in the choroid plexuses or in the meninges or with their passage into the cerebrospinal fluid.

Inhibiting Action of Roentgen Rays on Experimental Vaccination.—Le Fèvre de Arric exposed the shaved skin of rabbits to roentgen rays. Fourteen days later smallpox vaccine was *applied to the pigmented region,* and *to the surrounding* skin. Only a few *pustules developed on the treated* region; the number of the pustules was considerable on the normal skin The phenomena observed with roentgen rays are analogous to those observed by Carnot, Camus and Bénard with ultraviolet rays.

Influence of Bacteriophage on Specific Agglutinability of Bacilli.—Bruynoghe and Dubois injected rabbits with cultures of typhoid or *pseudodysenteric bacilli treated with the same* bacteriophage Examination of the *animals' serums revealed* that the agglutinability of the different *micro-organisms* remained different in spite of the fact that the latter had been exposed to the same bacteriophage.

Experimental Changes in Color Index of Erythrocytes.—Royer observed a rise in the color index of erythrocytes in hemolytic anemia *in dogs,* caused *by cobra venom.* The increase reached its *maximum from one to three days* after the injection of the venom; thereafter it fell gradually, the index becoming normal in two weeks. It is presumed that a part of the liberated hemoglobin is retained by the erythrocytes. The size of the latter parallels the amount of the hemoglobin retained; consequently, it increases with the rise in the color index.

Sensitiveness to Morphine in Rats After Removal of Suprarenals.—Lewis and Torino noted an increased susceptibility to morphine in rats deprived of the suprarenals. The fact was confirmed by the glucose test.

Sensitiveness of Rats to Certain Substances After Removal of Suprarenals.—Crivellari found an increased sensitiveness to potassium cyanide, nicotine, acetonitril and histamine in suprarenalectomized rats.

Origin of Digestive Leukocytosis and of Leukocytosis Following Exercise.—From their researches, Viale and Di Leo Lira drew the conclusion that increase of hydrochloric acid in the blood appears to be the cause of digestive leukocytosis. Leukocytosis consecutive to muscular exercise seems to be due to an increase of potassium in the blood—not to that of lactic acid.

Glycolytic Action of Lactacidogen.—Viale and Combes explain the mechanism of alcohol formation in muscles. Lactacidogen forming in the muscles causes splitting of glucose. This is accompanied by formation of carbon dioxide and alcohol. The reaction is not influenced by hydrocyanic acid or by insulin.

Anaerobic Formation of Alcohol in Muscles.—A series of toads' muscles were kept at rest in air or in nitrogen. Another series of muscles were tetanized while kept in air or nitrogen. In tetanized muscles in nitrogen, the amount of alcohol was considerable. In the others, the traces were insignificant.

*Value of Dick Test in Scarlet Fever. G. Ichok.—p. 223.
*By-Effects of Smallpox Vaccination. Rivalier.—p. 231.

Cholecystitis of Amebic Origin.—Trabaud found living amebas in the gallbladder bile in several cases of cholecystitis. The diagnosis was suggested by the microscopic examination of the stools, by the blood picture and the emetine test. Amebic cholecystitis should be disinguished from amebic pseudocholecystitis, in which the liver is the seat of amebas. Amebic cholecystitis may be secondary to dysentery; it may also be primary. In the latter case, the amebas are carried from the intestine to the gallbladder by the blood stream. Emetine treatment supplemented by arsenicals should be administered and repeated at certain intervals.

Ichor from Vesicatory Blisters Used in Prevention of Infectious Diseases.—Modinos applied vesicants to convalescents from measles and from influenza, and used the blister fluid in prevention of the corresponding disease. A case is described in which it happened that fourteen children had been in contact with a child with measles. Children between 3 and 5 years of age were injected with 3 Gm. of the fluid; older children, with 5 Gm. About 20 Gm. of the fluid were obtained from two vesicatory blisters produced in another child of the family, recovered from measles. None of the children injected contracted measles; while, among the noninjected, two acquired the disease. He suggests the use of 1 cc. of the ichor for each year of age; 10 cc. for children up to the age of 15. A dose of 10 cc. of blister fluid from influenza convalescents was injected in patients with influenza. An attenuation of the disease was manifest. The dose should be tripled if the fluid is obtained from persons who have long been recovered from the disease. The ichor need not be decanted or heated. This method never caused any complications.

Nervous Disturbances from Intestinal Worms.—Nervous phenomena accompanying helminthiasis may be of the sensory, neuralgic, polyneuritic or rheumatic type. There also may be motor disturbances, appearing under the form of paresis or paralysis. The connection of convulsions with the presence of worms, Moutier says, is open to discussion. Meningitis from helminthiasis may simulate a tuberculous or a cerebrospinal meningitis. Mental disorders, such as night terrors or delirium, are observed. Infestation with ascarides may cause neurasthenia, characterized by a condition of pessimism and unfitness for any occupation. The verminous origin of the nervous disturbances is confirmed by their disappearance after expulsion of the parasites. If they persist, it is clear that the presence of the worms was a coincidence.

Measures for Prevention of Serum Accidents.—Pignot points out the measures capable of averting morbid phenomena after injections of a serum. The use of heated, preserved or purified serums may avert accidents developing after the first injection. In case of subcutaneous reinjections, first 5 cc. of the serum should be introduced slowly; the total therapeutic dose is injected fifteen minutes later. In case of intraspinal reinjections, first 1 cc. of the serum is injected; the therapeutic dose, two hours later. It is well to have the reinjections preceded by an intramuscular injection of 0.005 cc. of a 1:1,000 solution of epinephrine. Bourcard's method is valuable in testing the patient's susceptibility toward a serum. One-tenth cubic centimeter of the serum is injected subcutaneously into the forearm. In case of an existing hypersensitiveness, an intense local reaction is observed. Otherwise, the reaction is nil.

Value of Dick Test in Scarlet Fever.—From a comparative study of the researches of the Dicks and Di Cristina, Ichok draws the conclusion that the Dick test and preventive vaccination with streptococcus toxin are of greater value in practice.

By-Effects of Smallpox Vaccination May Be Averted.—Rivalier lists the measures by means of which by-effects of smallpox vaccination may be avoided or at least reduced. Hence, he says, there is no ground for the antivaccinationists' alarm.

Presse Médicale, Paris

35: 369-384 (March 23) 1927

Lithiasis of Common Bile Duct and Hepatic Ducts. M. Chiray and R. Degos.—p. 369.
*Appendicitis on the Left Side. R. Bloch.—p. 373.

Two Cases of Appendicitis on the Left Side.—In one of Bloch's patients with appendicitis, the pain was on the left side, while the cecum was situated normally. In the other patient, the pain was on the right side, although the cecum was situated in the left iliac fossa. The cases confirm the fact that there is a clinical and an anatomic form of left appendicitis. The clinical form is observed when the appendix is long and is situated transversely. In these cases inflammation is limited to the extremity of the organ. The diagnosis of a left appendicitis may be made by the aid of roentgen rays; usually it is established only at operation. A median incision for appendectomy is advisable in cases in which the appendix is presumably lodged outside of the right iliac fossa.

35: 385-400 (March 26) 1927

*Local Anesthesia in Treatment of Visceral Pains. M. Roch and E. Frommel.—p. 385.
Serum Treatment of Scarlet Fever. C. Zoeller.—p. 385.
Study of Pigments. L. Binet.—p. 388.

Local Anesthesia in Treatment of Pains Connected with Diseases of Viscera or of Serous Membranes.—Roch and Frommel inject 10 cc. of a 0.5 per cent solution of procaine hydrochloride subcutaneously in the region where the pain is most severe. They used the method with good results in eighteen patients with angina pectoris, acute pericarditis, pleuritis, cholecystitis, biliary colics, gastric ulcer, cancer of the stomach and splanchnoptosis with lumbar pain. Violent pains were relieved for several hours, sometimes permanently. Another advantage of the treatment consists in bringing about relaxation of muscles, which facilitates palpation. The disappearance of the pain, however, should never be an excuse for deferring an urgent operation.

*Influence of Food on Blood, Urine and Feces. E Tschopp —p 223.

Fever Treatment of General Paralysis.—Wurz urges early treatment with malaria It is wrong to wait for the development of grave mental symptoms

The Blood After Roentgen Irradiation.—Gigon and Ludin found that food influences the reaction of rabbits to roentgen irradiation The total carbon and nitrogen of the whole blood become lower and the blood sugar higher on an ordinary diet, on oats or during fasting, regardless of the dose of rays applied Rabbits fed on green fodder react with a marked increase in the total carbon (up to sixty times more than could be accounted for by the hyperglycemia), without a proportionately large increase in nitrogen.

Influence of Food on Blood, Urine and Feces.—Tschopp noted a considerable increase in blood cholesterol in rabbits fed on oats The food also had a distinct influence on the calcium and phosphorus metabolism He believes that the differences in the reaction of irradiated rabbits (mentioned in the preceding abstract) may be due to changes in the cholesterol metabolism

*Location of Spirochaeta Pallida in General Paralysis A. C. Pacheco e Silva —p 227
The Tabetic Bladder and a New Cystoscopic Sign. S. Perlmann.—p. 230.

Location of Spirochaeta Pallida in General Paralysis.—Pacheco e Silva studied the brains of fifty-six patients with general paralysis, three of them inoculated with malaria. Illustrations show the condition found. The spirochetes do not enter the nerve cells. On the contrary, these act as a barrier. After some cells have been destroyed, the organisms migrate elsewhere They accumulate around capillaries and small vessels, crossing from these to the nervous structures. Spirochetes prefer bifurcation points for crossing, as it seems easier to break through there. They were especially abundant in the second and third layers of the pyramidal cells at the level of the frontal lobe. They were rarely found in the centrum ovale or at the level of the meninges, and never around meningeal vessels. They were detected in the lenticular nucleus and in all the cortical regions, but not so often as in the frontal region. It was difficult to discover any in the cerebellum, even when the lesions were conspicuous. They were found in the brain stem in a case of taboparalysis, and in the medulla in a number of cases of taboparalysis and tabes. Intra-arachnoid therapy is not consistent with these observations.

Experience in Giving Advice on Marriage Raecke —p 463

Hemophilic Disturbances of Blood Clotting —Frank and Hartmann found that the action of blood platelets is the same in normal and in hemophilic subjects Differences are due only to the adsorption of blood plasma, and they disappear after repeated washing of the platelets The blood in hemophilia contains substances which inhibit the change of proserozyme into serozyme Thrombin forms from the latter in the presence of calcium by the action of kinase contained in blood platelets Injections of normal whole blood or normal blood plasma, from which the proserozyme has been removed by treatment with tricalcium phosphate, restore the normal coagulability of the blood for a day or two

Arsphenamine-Fast Recurrens Spirochetes. — Kritschewski *found considerable differences in the therapeutic dose* necessary for different strains of recurrens spirochetes This is especially striking if the brain of the animal is examined for proof of cure

Serodiagnosis of Cancer.—Kahn describes the technic of his "albumin A reaction" for serodiagnosis of cancer Fregonneau reports 87 5 per cent correct, 6 5 per cent doubtful and 6 per cent incorrect results in 440 tests (including 121 malignant tumors)

Glycolysis and Phosphates —Abraham and Altmann found a more pronounced glycolysis in the blood after the addition of a phosphate The loss in dextrose was greater than the increase in lactic acid They believe that this may be due to formation of a diphosphoric-glyceric acid

Raynaud's Disease and Pituitary.—Bloch reviews the relation of the pituitary to Raynaud's syndrome He had an excellent result in one case from injections of extract of the posterior lobe The injections were given at first two days apart, and later at longer intervals

Injury to Kidneys by Roentgen Rays—In 1921 Domagk observed the case of a child who died of nephritis about six months after roentgen-ray treatment of tuberculosis of the mesenteric lymph nodes He attributed the nephritis to roentgen-ray injury to the kidneys, and tried to verify his hypothesis experimentally In irradiated rabbits he found the tubules atrophic, while the glomeruli were comparatively well preserved The changes in the epithelium were more marked in overfed animals than in animals on a low diet He observed three more cases in human subjects in whom the kidneys were probably injured by roentgen-ray treatment of abdominal tumors Peculiar scars in the kidney were highly suggestive of it

Preventive Vaccination Against Tuberculosis —Langer believes that it is possible to immunize against tuberculosis with dead bacilli He recommends intracutaneous injection of a vaccine prepared from young cultures killed by boiling During the last three years, he traced the fate of fifty infants in tuberculous families who had been immunized by his method All of them are apparently healthy, while the average mortality of infants in such families ranges from 20 to 30 per cent

Effect of Irradiation of the Ovary on Offspring..—Theoretically, and referring to animal experiments, Nurnberger discusses the question of injury to the offspring of women whose ovaries had been exposed to sterilizing doses of roentgen rays either before or after the ovulation concerned Injuries to the phan and the gene are considered separately There is not sufficient evidence in proof of the former His researches indicate that injury to the gene, if admitted, is of a recessive character and depends on more than one hereditary factor He elaborates some of the implications of these statements. Martius agrees that from observations on human beings it is as yet impossible to draw safe conclusions Animal experiments show all degrees of injury to the phan The analogy to injury to the germ cell from alcohol appears to be close, and from this it seems extremely probable that roentgen rays act as a germ poison, in the sense of injury to the phan, transmittible through several generations, but not, properly speaking, hereditary On the question of injury to the gene, we are still entirely in the dark It has been shown in experiments on insects that roentgen rays influence chromosome division, but the direction that the influence will take is not predictable Flaskamp maintains that the question of irradiation of the human ovary belongs in the realm of practical experience and not in that of speculation He regrets that in the reports of much experimental work no distinction is made between weak irradiation and a dose that produces temporary sterility He is disinclined to accept many reported cases of "roentgen-ray injuries" to the child as due to ovarian irradiation In the interval between irradiation and amenorrhea, conception is to be avoided, if it takes place, the pregnancy is to be interrupted, for the possibility of impregnation of an injured ovum exists at this time As to the rays acting as a germ poison, it has yet to be proved that germ poisons exist

Results of Surgical Treatment of Carcinoma of the Cervix.—Wille states that Wertheim's radical operation is the treatment of choice at the Charite women's clinic In 308 cases treated by surgery between 1916 and 1920, 45 8 per cent show a five year cure For the last of these years, the percentage was 56 05, for patients operated on in an early stage, 76 per cent, for patients whose tumors were already in the borderland stage between operability and inoperability 25 per cent Franz extended the limits of operability farther than do many Infiltration of the parametrium was not a contraindication, unless bone was involved Involvement of the vaginal wall, slight mobility of the uterus, complicating myoma or adnexal changes were not permitted to interfere, but carcinomatous involvement of the bladder was a contraindication No woman over 65 years old was submitted to operation Fourteen women were under 30 years of age

Is There a Tubal Sphincter?—Schneider and Eisler publish a series of roentgenograms of the uterus and tubes (obtained with a contrast fluid) which, they believe, demonstrate the existence of a sphincter at or near the uterine end of the tube

Function and Structure of the Umbilical Vein—Wharton's jelly does not contain capillaries Experiments in vitro indicate that it receives its nourishment by diffusion from the umbilical vein, which in certain respects differs anatomically from other blood vessels (arteries or veins) There is also a difference between the portion of the vein that lies within the child's body and the portion that lies without The former contains little muscle The walls consist of firm, collagenous connective tissue, with an abundance of elastic fibers Inside the abdomen, the vein resembles other veins in the new-born The difference in structure appears to be related to the permeability of the walls of the vein during this portion of its course.

"Spontaneous Combustion."—Josephson discusses the question of spontaneous combustion in fictional literature (Marryat, Dickens and—more surprising—Zola) and in science. The possibility of spontaneous complete combustion in obese alcohol addicts had been regarded as a rare, but unquestionable fact up to 1848, when a famous criminal case gave the occasion for Liebig's annihilatory criticism Chronic alcoholism frequently leads to obesity, and fat burns more easily than other tissues Acute intoxication renders the subject insensible to pain and the intoxicated person may catch fire without noticing it. These are the only facts in the number of alleged authentic reports on spontaneous combustion

Treatment of Diabetic Coma.—Faber and Holst treat diabetic coma by insulin alone—without the addition of carbohydrates or other food When the patient improves, they start a vegetable diet with increasing amounts of fat In some patients, small doses of insulin (for instance, 24 units) may be sufficient In other cases, more insulin is necessary—for example, 64 units to start with, 40 units five hours later, and 20 units after six hours more, according to the blood sugar level.

Epidemic Hepatitis.—An epidemic in Finland is considered by Ehrstrom as providing justification for Lindstedt's theory that a large proportion of cases of catarrhal jaundice are manifestations of a specific epidemic hepatitis which is not identical with Weil's disease It is possible that some cases of acute atrophy of the liver and even biliary and hypertrophic cirrhoses may belong to the same group

Pneumothorax Treatment of Abscess.—Jacobaeus reports three successful cases of treatment of pulmonary abscess by pneumothorax

Hemodynamics in Rabbits in Health and Pneumonia—Leegaard found that the quantity of blood expelled by the heart in a given unit of time as well as in a single beat, is considerably increased in rabbits suffering from pneumonia The work of the heart is augmented because of this increase in minute-volume The respiratory consumption of oxygen is increased during pneumonia The difference between the oxygen content in blood from the left and from the right side of the heart is less than normal The increase in the respiratory consumption of oxygen and in the output of blood from the heart may be ascribed partly to the local process in the lungs For the main part, however, it must be viewed in connection with more general factors (increased metabolism).

*Scurvy in Unmarried Men. E. Meulengracht—p 165.

Scurvey in Unmarried Men.—Meulengracht reports eight cases of scurvey caused by insufficiency of vitamin C in the food. The patients were unmarried laborers, and had principally been on a diet consisting of bread, butter, cheese, coffee, beer and brandy. The most prominent symptoms were large extravasations of blood in the subcutaneous tissue of the extremities. Hemorrhages into mucous membranes or the internal organs were not observed. Most of the patients presented typical gingivitis, with painful teeth, and anemia. The prodromal symptoms were feebleness, depression, drowsiness, chills, palpitation of the heart and loss of appetite. Six lemons, fresh vegetables and fruit were given daily, in addition to the normal diet. The scorbutic symptoms rapidly disappeared. Administration of iron increased the hemoglobin.

Experiences in a Malignant Sore Throat Epidemic.—In 1926, Hvidt studied 2,000 cases of sore throat among a population of 18,000, in Kolding, Denmark. Only twelve cases proved fatal. Hemolytic streptococci were isolated from the patients, but diphtheria bacilli were not found. The lesions were mainly in the tonsils. Twenty patients developed erysipelas of the face as a sequel of typical tonsillitis. The disease showed a tendency to formation of peritonsillar and lingual abscesses Morphine was avoided in the treatment. Intravenous injections of an acridine preparation had a favorable effect in cases with signs of septic infection.

Subacute Inguinal Lymphogranulomatosis M. C Lottrup—p 209.
Treatment of Erysipelas by Injection of Protein. J. C. Gerdes—p. 210.

Gout.—In the treatment of gouty arthritis, Faber differentiates three different stages of the disease: acute attacks, joint deformities and chronic anomalies of metabolism. In acute attacks, the patient should remain in bed. From 1 to 1½ liters of milk and from 3 to 5 mg. of colchicine in four doses at half hour intervals are given daily. The administration of colchicine is continued until diarrhea sets in; it is then discontinued The patients became free from pain in almost every case, and the acute attacks disappeared in a few days. In case of chronic metabolic disturbances, the patients should remain on a purine free diet. Treatment of chronic deformities of the joints does not differ from that in similar diseases In the infectious types of chronic polyarthritis, it is important to locate and remove the focus of infection In cases in which this is impossible, protein therapy gives good results. In a majority of polyarthritic cases, physical therapy proves useful. Salicylic preparations and cinchophen relieve the pain. The general arthritic condition is usually produced by pathologic conditions of the blood, muscles, or connective or subcutaneous tissues. In cases of asthenia and neurasthenia with symptoms of rheumatism, bromine and other sedatives act favorably, whereas baths or massage may cause exacerbations. Myopathy and infiltrations are counteracted by massage.

THE DIET IN THE TREATMENT OF CARDIAC FAILURE *

FRED M. SMITH, M.D.; R. B. GIBSON, PH.D.
AND
NELDA G. ROSS, M.S.
IOWA CITY

The importance of the diet in cardiac failure has apparently not been fully appreciated. The Karell diet is usually mentioned in the discussion of the treatment of advanced cardiac failure with edema. While this diet greatly promotes the elimination of excess fluid, it is obviously inadequate because of its low energy value. Various modifications of the Karell diet have been recommended, but in each instance the caloric value has not been sufficient to maintain a normal metabolism.[1]

In advanced cardiac failure, not only the heart but also the entire body is in an exhausted condition. The diet should thus not impose an excess load but still provide sufficient energy. The sodium chloride should be reduced and the liquid intake restricted when edema is present, though not to the degree ordinarily practiced. Milk is a very desirable constituent of the diet because of the ease with which it is assimilated and its low sodium chloride content. Other foods, however, are apparently equally efficient. During the World War, the scarcity of milk in some countries prohibited its use in the diet of cardiac failure and led to the employment of substitutes which, in some instances, were reported to produce more satisfactory results than the Karell diet.[2] The liquid intake was limited to 1,000 cc. and was given in the form of water and fruit juices. To this was added 1 Kg. of potatoes or bananas (the former were cooked without salt). The diet was served in five portions daily. The major portion of the energy was provided by carbohydrates. The favorable results, however, were ascribed to the low sodium chloride and the high potassium content of the potato and banana. The explanation is in accord with the use of potassium and calcium salts in the treatment of edema, especially of nephritic origin.[3]

The importance of carbohydrate as a source of energy to the body and particularly to the heart suggests the use of sucrose and dextrose solutions in the treatment of cardiac failure. Goulston,[4] Carter,[5] Dingle[6] and MacGregor[7] have observed marked improvement in patients with advanced cardiac failure following the addition of sucrose to the diet. They recommend that from 2 to 4 ounces be taken daily. In some instances, the cardiac function was restored after the usual forms of diet and drugs had failed. Büdingen,[8] Pfalz[9] and others have recorded favorable results after the administration of dextrose solution intravenously.

More recently, Edmunds and Cooper[10] have studied the effects of dextrose solution on the circulatory failure produced by the subcutaneous injection of diphtheria toxin. In those animals in which the circulatory collapse was extreme and in which the usual cardiac stimulants had very little effect, the introduction of dextrose solution (10 per cent) into the vein was followed by marked improvement in the heart and an increase in the blood pressure. They regarded the dextrose as a life-saving measure in many instances, and state that they were able to save the animal if the dextrose was injected into the vein before the heart stopped. These results were attributed to the energy provided by the dextrose.

Clinical and experimental observations seem to indicate that milk and carbohydrates, particularly those forms of the latter which are easily assimilated, should constitute the major portion of the diet in cardiac failure. A diet was thus constructed which has an energy value of 2,100 calories and consists of 44 Gm. of protein, 110 Gm. of fat and 222 Gm. of carbohydrate. It is served in the form of milk, cream, butter, eggs, vegetable purées, cooked cereals and fruit juices. The carbohydrate is further increased by the addition of sugars, as dextrin-maltose, dextrose and lactose. Small and frequent feedings are given to avoid gastric retention and fermentation. When edema is present, the liquid intake is limited to 1,500 cc., and the salt is reduced to a minimum. Usually on the third or fourth day other foods, as jelly, crackers (salt free), toast and stick candy, are added. Later, about the eighth day, depending on the condition of the patient, puréed fruits and additional puréed vegetables are incorporated in the diet. Gradually, the consistency of the food is changed from that of the soft to the light diet. In some instances, following the elimination of the excess fluids, particularly in those patients who are greatly undernourished, the energy value of the diet is increased to approximate 3,000 calories. However, when the patient is obese, the diet is sufficiently reduced to permit a gradual loss in weight.

The efficiency of the diet was studied in the following manner:

All patients with cardiac failure, with individual exceptions, were treated in the same way. They were put to bed at absolute rest. When necessary, codeine or morphine was administered hypodermically at bedtime to promote sleep. Cascara or other mild laxatives were employed when needed to produce a daily bowel movement. From 15 to 20 minims (0.9 to 1.25 cc.) of tincture of digitalis was prescribed three or four times daily, depending on whether or not the patient had previously taken the drug. The routine hospital soft diet was served. The liquid intake was limited to 1,500 cc., and the urinary output was recorded. The patient was weighed daily when the condition permitted. If after a period of from five to seven days there was no demonstrable change in the general condition and the weight remained stationary, the cardiac diet was prescribed. The favorable influence of the diet is illustrated by the following patients:

REPORT OF CASES

Case 1.—H. B., aged 61, admitted to the University Hospital, May 18, 1926, because, chiefly, of shortness of breath and swelling of the feet, stated that he had been short of breath for one and one-half years. The clinical picture was that of advanced cardiac failure. The heart was markedly enlarged. There was a basal diastolic and apical systolic murmur. The systolic blood pressure was 160 and the diastolic, 48. There was a general anasarca. The urine showed considerable albumin and occasional hyaline and granular casts. In the electrocardiogram the T deflection was negative in each lead. The weight on admission to the hospital was 165 pounds (75 Kg.). The routine treatment was prescribed. The patient complained of having a diarrhea on the second day. During the following ten days he had from five to eleven watery stools daily, and it was necessary to administer powdered opium to control the diarrhea. After the diarrhea subsided, the weight gradually increased and on the twenty-first day was 171 pounds, or 77.6 Kg. (chart 1, upper curve). The cardiac diet was then prescribed. Thereafter, there was a gradual loss in weight to 144 pounds (65.3 Kg.). The excess fluids had been eliminated, and the symptoms of cardiac failure had disappeared. Coincident with the reduction in weight there was an increase in the daily urinary output to 1,800 cc.

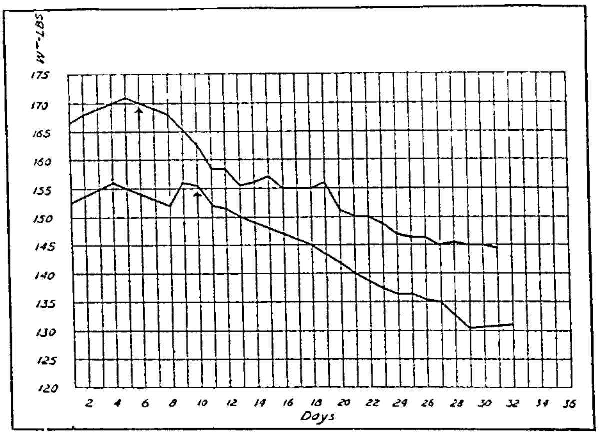

Chart 1.—In this and subsequent charts, arrow indicates day on which the cardiac diet was begun. Upper curve, case 1. The patient was not weighed between the fifth and eighth day because of his general condition. Lower curve, case 2.

Case 2.—F. M., aged 46, admitted to the University Hospital, March 23, 1926, complained, on entrance, of shortness of breath and substernal pain, which radiated to the arms. This was his sixth admission to the hospital. When first seen in July, 1923, he complained of shortness of breath on slight exertion. He was found to have a tertiary syphilis involving the central nervous system and the aorta. The aorta was dilated and the heart increased in size. At the time of the last admission, the patient was very cyanotic and dyspneic. There was a marked pulsation of the carotid arteries and a heaving of the entire precordium. The apex impulse was located in the sixth interspace at the anterior axillary line. The width of substernal dulness in the second interspace was 9 cm. There was a rough systolic and a faint diastolic murmur at the base, and a gallop rhythm at the apex. There were numerous moist râles in the bases of both lungs. The liver extended 6 cm. below the costal margin. The systolic blood pressure was 190 and the diastolic, 120. The urine contained a trace of albumin and occasional hyaline and granular casts. The electrocardiogram showed a marked left ventricular preponderance, and the T deflection was negative in leads I and II. The Wassermann reaction of the blood was strongly positive. The patient weighed 144 pounds (65.3 Kg.). He was treated in the usual manner, except that one-half ounce of magnesium sulphate was given daily before breakfast. During the first ten days the weight decreased to 135 pounds (61 Kg.), and there was some improvement in the general condition. Later, however, the breathing became more difficult, the liver extended to the umbilicus, fluid appeared in the abdominal cavity, and the weight increased to 151 pounds (68.5 Kg.). Theophylline was administered, and a Karell diet ordered. There was some reduction in the weight. The diet was discontinued on the fifth day because of weakness of the patient. The weight gradually increased, and the abdominal cavity became more distended. The patient was very uncomfortable, and it seemed advisable to prescribe morphine during the day in addition to that at night. An abdominal paracentesis was done, and 2,500 cc. of clear straw colored fluid was removed. The fluid, however, rapidly returned. The magnesium sulphate was then discontinued and the cardiac diet ordered. The weight at this time was 155 pounds, or 70 Kg. (chart 1, lower curve). Thereafter there was a gradual loss of weight, the abdomen decreased in size, and the general condition improved. In three weeks, the weight was 137 pounds (62 Kg.), the fluid had practically disappeared from the abdominal cavity, and the liver edge receded to 6 cm. from the costal margin. The weight was further reduced to 131 pounds (59.4 Kg.). The edema had disappeared from the extremities, and there was no demonstrable fluid in the peritoneal cavity.

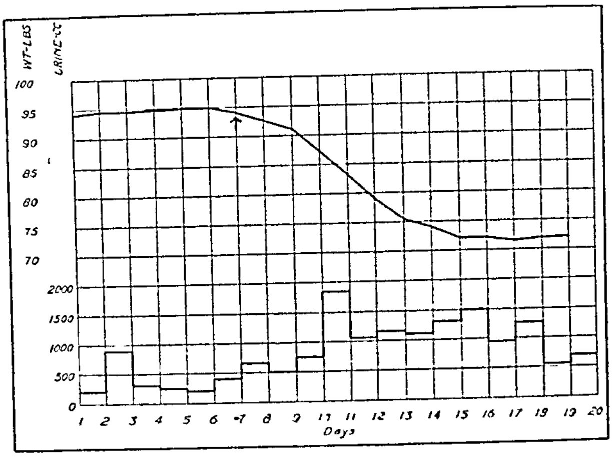

Chart 2.—Case 3.

Case 3.—E. M., aged 15, admitted to the University Hospital, July 25, 1926, because of shortness of breath, increase in the size of the stomach and swelling of the feet, had had rheumatic fever in December, 1925, involving several joints. Three days following the onset of the illness, he experienced pain in the precordium and became very short of breath. He was confined to bed for three months. In June the shortness of breath returned, the abdomen increased in size, and swelling of the feet was noticed. The examination indicated that the heart had been extensively injured by the rheumatic infection and that there was very probably an adhesive pericarditis. The abdomen was distended with fluid, and the edema of the legs extended above the knees. The temperature on admission was 101.2 F. and the pulse rate 135 a minute. The weight was 95 pounds (43 Kg.). During the first seven days in the hospital the weight remained stationary and the daily urinary output, except for one day, ranged from 200 to 400 cc. (chart 2). The temperature varied from 98.6 to 100. The pulse averaged approximately 120 a minute. The cardiac diet was ordered on the seventh day. Thereafter the weight rapidly decreased, and on the fourteenth day was 74 pounds (33.6 Kg.). Coincidently, the temperature subsided, the pulse rate diminished, and the urinary output increased.

CASE 4.—H. T., aged 54, when admitted to the University Hospital, Aug. 7, 1926, stated that he had been short of breath for more than two years and had noticed swelling of the feet since April. He was very dyspneic; the apex impulse was in the axilla, and the cardiac tones were distant. The heart rate was 120 a minute and regular except for an occasional premature contraction. The liver extended to the umbilicus, fluid was demonstrated in the peritoneal cavity, and there was extensive edema in the legs. The systolic blood pressure was 186 and the diastolic, 122. The urine contained albumin and a few hyaline and granular casts. The electrocardiogram showed a negative T deflection in leads I and II. The weight on admission was 213 pounds (96.6 Kg.). Six days later it was 213 pounds (chart 3, lower weight curve). The cardiac diet was ordered. During the next week the patient lost 13½ pounds (6 Kg.). The cardiac symptoms disappeared. He was discharged, September 24, weighing 195 pounds (88.5 Kg.). He did not follow instructions after leaving the hospital and returned again, October 27, in much the same condition as when first seen. The weight was 222 pounds (100.7 Kg.). Seven days later it was 220½ pounds, or 99.7 Kg. (chart 3, upper weight curve and urine curve). The cardiac diet was again prescribed, and there was a reduction in weight similar to that observed during the first period in the hospital.

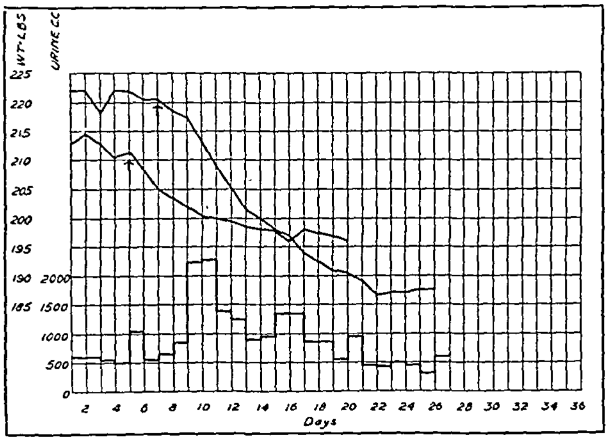

Chart 3.—Case 4: Lower weight curve, first admission to hospital; upper weight curve and urinary output, second admission.

CASE 5.—S. P., aged 66 (?), was first admitted to the University Hospital, Oct. 1, 1924, with shortness of breath, increase in the size of the abdomen and swelling of the feet. The shortness of breath was first noticed in March, 1924. He was examined and told that he had high blood pressure. When seen following the admission to the hospital, the conditions were those of advanced cardiac failure and extensive edema of the extremities. The heart was very large, the tones at the apex were muffled, and a rough blowing murmur was heard. The aortic second sound was moderately accentuated. An occasional premature contraction was noted. The liver extended 10 cm. below the costal margin. The systolic blood pressure was 110 and the diastolic, 80. The urine showed albumin and hyaline and granular casts. The T deflection of the electrocardiogram was negative in each of the three leads. The patient made a slow recovery and was discharged from the hospital, December 9, in fairly satisfactory condition. He returned home and was able to do light work until May, 1926. The shortness of breath returned and rapidly progressed until he was again admitted to the hospital, July 5, 1926. The patient seemed even more dyspneic than at the former admission, and there was a general anasarca. He was not weighed the first day because of the discomfort that slight exertion produced. The weights on the fourth and fifth days were 160½ and 161 pounds (72.8 and 73 Kg.), respectively (chart 4). The cardiac diet was begun on the sixth day, and during the following seven days the patient lost 21½ pounds (9.8 Kg.). The urinary output increased from 650 to 2,150 cc. The excess fluid was practically eliminated. The following day the patient had a cerebral accident and died three days later.

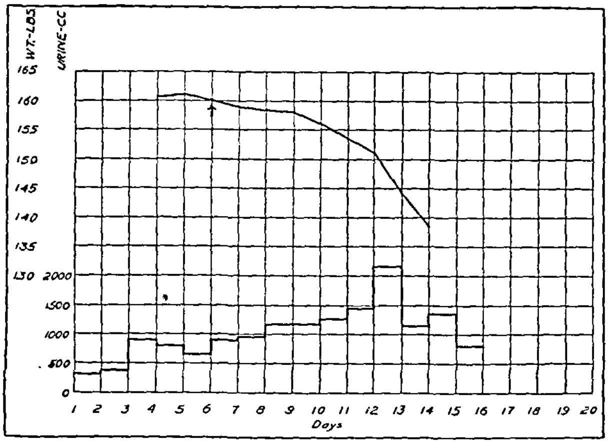

Chart 4.—Case 5.

COMMENT

These five patients were similar in that each had the clinical manifestation of advanced cardiac failure with extensive edema or even general anasarca. The treatment was the same in all instances. The duration of the control period was sufficient to permit digitalis effects before the cardiac diet was prescribed. It is questionable whether any of the patients would have eliminated the excess fluids without the change in diet. The course in two cases, prior to the time of instituting the cardiac diet, was progressively downward, and there was no appreciable improvement in the remaining three. The results observed in the second patient were most striking. It is to be recalled that theophylline, magnesium sulphate and the Karell diet did not alter the clinical course. The magnesium sulphate was discontinued when the cardiac diet was ordered.

These results emphasize the importance of diet in the treatment of cardiac failure. They demonstrate that a change in this feature of the treatment alone may be sufficient to promote the elimination of the excess fluid after the usual remedies have failed. The effectiveness of the diet is believed to be due to the energy value and the form in which the food is given. It is felt that patients with cardiac failure, especially those in whom the condition has existed for some time, should have at least a diet that will maintain a normal metabolism. This requirement has not been met, particularly when the Karell diet and its various modified forms have been employed. It is possible that insufficient nourishment may be responsible for the poor response to digitalis in some instances. The observations of Edmunds and Cooper[10] support this conception. It is to be recalled that digitalis and other cardiac stimulants had very little effect in the advanced circulatory collapse produced by the subcutaneous administration of diphtheria toxin, whereas following the introduction of glucose into the vein the action of the drugs was far more favorable. This possibility was further suggested by a patient recently under observation. He had the clinical manifestation of advanced cardiac failure with extensive edema of the extremities when admitted to the hospital. The auricles were fibrillating, and the cardiac rate varied from 130 to 140 a minute. He ate very little because of nausea and the distaste for food during the first five days in the hospital. He was given more digitalis than is ordinarily employed, yet there was no change in the cardiac rate and the course of the condition was progressively downward. At this time the administration of glucose (10 per cent solution) by rectal drip was begun. The following morning the patient voluntarily stated that he felt considerably better and expressed a desire for food. The cardiac rate rapidly decreased and the urinary output increased. The glucose solution was discontinued after another twenty-four hours, and recovery thereafter was uneventful.

The form in which the food is given is probably as important as the energy value of the diet. It is obvious that the food should not only have a low salt content, particularly when edema is present, but also be provided in a form that may be assimilated without imposing an excess load on the gastro-intestinal tract and the heart. While the favorable results of the cardiac diet are no doubt in part due to the low salt content, the energy supplied by the carbohydrates in the form of sugars is believed to be an important factor.

During the last year, the cardiac diet described has been employed in more than fifty patients. In only two was there excessive gas formation, and one had diarrhea. In each instance the conditions were controlled by temporary reduction of the carbohydrates. Later, the carbohydrates were increased without provoking a diarrhea or producing excess gas. The fruit and vegetable content of the diet is sufficient to produce usually one or two bowel movements daily. Rarely was it necessary to administer laxatives. It has frequently been necessary to vary the diet because of the taste or condition of the individual. In one patient with hyperthyroidism and a basal metabolic rate of plus 48 per cent, the protein was increased to 65 Gm. and the energy value to 5,500 calories. Two patients had a dislike for milk. In each, the milk was reduced and the protein replaced with an additional egg. Later, one of these patients overcame the distaste for milk and took any amount given him. An occasional patient objects to sweetened beverages; either jelly or stick candy was substituted for the sugars for a few days. Later, the patient was often willing to take additional sugar in the other foods.

In some of our patients, the twenty-four hour urinary excretion of nitrogen, chlorine and creatinine was determined. In one case (table 2) the figures for sodium, potassium and phosphorus are also included. The values for nitrogen and chlorine are, in general, in accord with the earlier workers. There was no evidence of a toxic nitrogen catabolism except in one patient. The chlorine excretion was increased with the elimination of the edema. The patients were undoubt-

* The composition of the weighed diet (calculated) is protein, 44 Gm.; carbohydrate, 220.6 Gm.; fat, 109 Gm., and calories, 2,076. Additions to the diet are made between the fourth and the tenth day, beginning with toast, jelly, salt-free crackers, and butter; sieved fruit and baked potato are included later. If the diet is first increased on the fourth day, the patient may be receiving as final additions to the basic diet protein, 37 Gm.; carbohydrate, 112.3 Gm.; fat, 25 Gm., and calories, 718, as follows: breakfast, toast, 20 Gm.; butter, 10 Gm.; jelly, 20 Gm.; dinner, baked potato, 1, sieved fruit juice, 100 Gm.; toast, 20 Gm., butter, 10 Gm., supper, sieved fruit, 100 Gm., toast, 20 Gm.; butter, 10 Gm. Stick candy may be substituted anywhere in the diet for the equivalent amount of sugar.

† Milk, 100, cream, 66, sucrose, 5; dextrin maltose, 10, and a half junket tablet. When junket is served, the milk at 7 p. m. is reduced to 100.

‡ Pureed spinach. Other vegetables may be substituted.

* First day of cardiac diet.

† Diet was increased on this and subsequent days.

edly in nitrogen equilibrium or a plus balance was indicated, even when the body weight remained stationary. The creatinine excretion increased with the onset of the diuresis and remained fairly constant thereafter. The results of this determination prior to the onset of the diuresis suggests the advisability of a further study of the creatinine during the development of the edema.

The significance of the sodium ion in edema formation has received clinical recognition only in recent years. Most of the data have been interpreted on the basis of chlorine determinations calculated as sodium chloride. Keith and Whelan[11] have found that sodium and chlorine ions are usually excreted in molecular proportions in the diuresis produced by merbaphen in normal persons and in noncardiac edema cases.

It is to be noted that there was an increase in the excretion of potassium and phosphorus along with sodium chloride during the diuresis. Gamble, Blackfan and Hamilton[12] regard the excess excretion of the sodium and potassium as indicating the source of the fluids eliminated. They believe that the sodium comes from the extracellular fluid and is the first to be moved, while the potassium is of intracellular origin.

The blood uric acid was usually increased in the arteriosclerotic patient, while the creatinine and urea nitrogen were within normal limits. As the clinical condition improved, the uric acid decreased.

SUMMARY

The importance of diet in the treatment of cardiac failure has not been fully appreciated.

The Karell diet, which is usually mentioned in the treatment of advanced cardiac failure, does not provide sufficient energy. The diet here described has been valuable in the treatment of advanced cardiac failure, particularly when extensive edema is present. This diet has an energy value of 2,100 calories, and consists of 44 Gm. of protein, 110 Gm. of fat and 222 Gm. of carbohydrate. The fluid intake is limited to only 1,500 cc., and the salt is reduced to a minimum.

This diet has been employed in the treatment of more than fifty patients, in whom the change in the diet alone effected an elimination of the excess fluids, with an associated improvement in the general condition. The efficiency of the diet is believed to be due to the low salt content, and the easily available energy provided by the carbohydrate, particularly in the forms of sugar.

Renal Tuberculosis.—Tubercle bacilli reach the kidney either by the blood stream or by the lymphatics, and of these two routes the hematogenous is undoubtedly the commoner. The exact site of the initial lesion in the kidney is disputed. The peculiar arrangement of the intrarenal arteries favors a cortical lesion, but clinically, though many tubercles are seen in the cortex, the grossest lesion is nearly always at the base of a papilla. The lymphatics are considered by some to be the means of infection in those cases which are secondary to quiescent pleural and pulmonary tuberculosis. The bacilli are thought to be carried in the lymphatics passing through the diaphragm by a retrograde current set up by pleural adhesions. Though primary lymphatic infection is doubtful, secondary infection may be conveyed from a diseased to a healthy kidney by the communicating channels between the two renal plexuses, or from an ulcerated bladder by the periureteral lymphatics.—Nitch, C. A. R.: Urogenital Tuberculosis, *Brit. M. J.*, May 14, 1927.

ANTISCORBUTIC VITAMIN CONTENT OF MILK OF STALL-FED COWS THROUGHOUT A YEAR

PROBABILITY THAT ENSILAGE IS AN IMPORTANT SOURCE OF THIS VITAMIN *

FLORENCE L. MacLEOD, Ph.D.
NEW YORK

Milk from cows which are stall-fed the year round is being used to some extent at the present time in the feeding of infants. In view of the fact that the milk from pasture-fed animals has been reported by most investigators to be richer in its vitamin content than that from animals without access to pasture, it has seemed of interest to test the milk from a herd of stall-fed cows for an entire year to determine its antiscorbutic potency. The greater antiscorbutic value of the milk of the pasture-fed cow is doubtless due to the antiscorbutic vitamin content of the fresh grasses which the animal receives, since the animal body probably does not synthesize this vitamin and is therefore dependent on its food to provide an adequate amount of it in its milk. Ensilage being the principal source of the antiscorbutic vitamin in the ration of the stall-fed cows, it appeared possible that animals fed an ensilage of good quality might produce a milk of high antiscorbutic value. It was also of interest to determine whether the antiscorbutic value of such milk would fluctuate from season to season or would remain reasonably constant.

Before the results of the present investigation are given, previous experiments dealing with the study of the antiscorbutic value of milk will be reviewed briefly.

REVIEW OF THE LITERATURE

Frölich,[1] in 1912, was the first to show by laboratory experiments that milk contained the antiscorbutic vitamin, vitamin C. He reported that guinea-pigs which were fed oats and raw milk ad libitum were normal after from 116 to 138 days on the diet.

Chick, Hume and Skelton,[2] in 1918, carried out the first work of a quantitative nature on the vitamin C content of milk. They found that guinea-pigs receiving from 30 to 50 cc. of raw cow's milk per animal daily died from scurvy in thirty days. If the amount of milk consumed averaged 50 cc., the lives of the guinea-pigs were prolonged to seventy-five days. When the amount of milk consumed averaged 85 cc. at the beginning and increased up to 130 cc. for the main period, good health was maintained and the weights of the animals were normal throughout the three months of the experiments.

Cohen and Mendel[3] reported, in 1918, that small amounts of raw milk did not prevent the onset of scurvy in guinea-pigs, while larger amounts caused the scorbutic symptoms to disappear.

Barnes and Hume,[4] in 1919, stated that from 100 to 150 cc. of raw milk per animal daily prevented scurvy in guinea-pigs weighing from 300 to 400 Gm. They also found some evidence which indicated that summer milk has a higher antiscorbutic value than winter milk.

Hart, Steenbock and Ellis,[5] in 1920, gave experimental proof of the relationship of the food of the cow

to the vitamin potency of the milk. They found that one guinea-pig out of three was protected from scurvy on 15 cc. of summer milk daily, and that two out of three on 30 cc. were protected, while on 50 cc. complete protection was obtained in every case. They also examined the milk from cows which had been kept on air-dried roughages and grains with no source of fresh, green vegetable tissue for several years. Seventy-five cc. of this milk daily protected guinea-pigs for eighteen weeks.

In 1919, Hess and Unger[6] stated that 80 cc. of milk was required to protect a guinea-pig from scurvy, and that at least one pint of fresh, raw milk daily was necessary to protect a baby from scurvy. Hess, Unger and Supplee,[7] in 1920, reported the results of experiments on the relation of fodder to the antiscorbutic vitamin content of milk. Five cows were kept on winter feed all winter, and in April were given a ration very low in its vitamin C content. After three weeks on this ration, one day's mixed sample of milk was dried by the roller process. The cows were then placed on pasture for three weeks and one day's mixed sample of the milk was dried. Five guinea-pigs receiving 80 cc. of the dry fodder milk per animal daily, all developed scurvy within twenty-one days and died of scurvy within fifty-six days. Three which were given 80 cc. of the pasture milk were alive after 120 days, and two of these showed mild scurvy.

Dutcher and his associates,[8] in 1920, reported experiments on the influence of the diet of the cow on the antiscorbutic properties of cow's milk. Two cows were placed on a vitamin-poor ration in the middle of January. The mixed milk was fed in varying quantities to several groups of guinea-pigs. June 1, the cows were given a vitamin-rich ration, and the experiment was repeated. Twenty cubic centimeters of summer milk per animal daily was found to be superior in antiscorbutic value to 60 cc. of winter milk. These authors secured evidence which showed a tendency for the milk to become poor slowly when the diet fed was low in vitamins, while the milk became of higher value almost immediately on ingestion of a vitamin-rich ration.

Cavanaugh, Dutcher and Hall,[9] in 1923, in studying the effect of the spray process of drying on the vitamin C content of milk, fed raw milk at levels of 20, 30 and 40 cc. per animal daily to guinea-pigs. The animals were fed for three months, and out of ten animals receiving 40 cc. of milk, four had mild scurvy.

Olson and Copeland,[10] in 1924, reported the results of studies on the influence of the diet of the cow on the antiscorbutic potency of the milk. They concluded that the vitamin C in milk has its origin in the feed of the cow, and that to maintain an adequate supply of this vitamin in the milk, good silage is important.

Hughes, Fitch, Cave and Riddell[11] reported recently, as the result of a long series of experiments, "that the vitamin C content of a cow's ration has little if any influence on the vitamin C content of the milk."

EXPERIMENTAL OBSERVATIONS

As stated before, experiments were performed to determine the antiscorbutic vitamin content of raw milk received from one dairy during an entire year from July, 1925, to July, 1926. The cows from which the milk was obtained received a diet which was believed to be an optimum one, and which was uniform throughout the entire year. Each cow during the year received on an average 9 pounds of the following mixture daily: bran, 400 pounds; hominy, 700 pounds; oilmeal, 300 pounds; gluten, 200 pounds; bone meal, 20 pounds; lime flour, 20 pounds, and salt, 40 pounds. In addition, each animal was given daily 5 pounds of New Jersey alfalfa hay, 4 pounds of ground Colorado alfalfa hay, 30 pounds of corn silage and 4 pounds of soaked dried beet pulp. The animals were outdoors in yards for a few hours in the middle of the day, weather conditions being suitable, but at no time had access to pasture.

The experimental procedure of Sherman, LaMer and Campbell[12] was followed in this work. According to their method, guinea-pigs which are known to be growing normally and which weigh from 300 to 350 Gm. are fed ad libitum a basal diet adequate in all other respects but devoid of vitamin C; and, in addition, the food to be tested in known amounts daily. The animals are continued on the experimental diet for ninety days, and the degree of scurvy determined at autopsy.

The basal diet used was approximately that of Sherman, LaMer and Campbell.[12] Its composition was: rolled oats, 39 per cent; bran, 20 per cent; skimmed milk powder heated, and freely exposed to air for four hours, at 110 C., 30 per cent; butter fat, 10 per cent, and sodium chloride, 1 per cent.

The amount of milk powder and butter fat used in this basal diet was reduced in proportion to the liquid milk fed. The diets were made up in such a way that each animal would receive daily approximately the same amount of milk solids from the sum of the liquid milk fed and the milk powder contained in the basal diet. In calculating the diets, the average intake of dry food was considered as 20 Gm. per animal daily, although it was found that the appetites of the individual animals for the basal diet were very different.

The milk was fed six days a week and was given by medicine dropper, two or three feedings being made during the day. The amounts given were calculated on the basis of a 300 Gm. initial weight. Every animal was weighed three times a week during the entire experiment. The scurvy scoring suggested by Sherman, LaMer and Campbell[12] and by Kenny[13] was used. Each animal on autopsy was given a numerical score which was based on deviations from the normal in the bony system; i. e., in the jaw, teeth, ribs and joints, and on hemorrhages occurring in the ribs, intestines, joints and muscles. According to the degree of scurvy, one plus sign, two plus signs or three plus signs were assigned to each part of the body examined for scurvy. By this method of totaling the plus signs, the maximum score possible is 24. When only a trace of scurvy was observable in any part of the body, a score of 0.5 was assigned.

During the year, three lots of skimmed milk powder were used in the basal diet. Each lot was tested to make sure that it was free from antiscorbutic vitamin. The control animals, which received the basal diet with no source of antiscorbutic vitamin, died of severe scurvy after an average of 22.4 days on the diet, with an average scurvy score of 18. The results found for these animals are given in table 1, and it can be seen that a seasonal difference was not found in their records.

The first series of animals were fed 30 and 50 cc. of milk daily per 300 Gm. initial weight. It was not found possible to feed more than 50 cc. of milk to a 300 Gm. guinea-pig during the day. The first experiments were started in July, 1925, and finished in October, 1925. The two animals receiving 50 cc. of milk daily in the first series were normal during the entire experiment and did not show signs of scurvy on autopsy. The one animal receiving 30 cc. of milk gained in weight steadily until the seventieth day of the experiment, when it began to lose weight rapidly and to show the symptoms of acute scurvy. This animal gave a scurvy score of 11 on autopsy.

TABLE 1.—*Data of Guinea-Pigs Restricted to Basal Diet*

Season	Number of Animals	Average Survival on Diet, Days	Average Scurvy Score at Autopsy	Degree of Scurvy
Summer....................	2	21	16	Very severe
Fall........................	3	23	16.5	Very severe
Winter....................	3	24	18	Very severe
Spring....................	1	19	19	Very severe

During the rest of the year, animals were fed on 30, 40 and 50 cc. levels. Among the animals receiving 30 cc. of milk daily, no deaths from scurvy occurred before the end of the ninety day experimental period. One animal died at eighty-eight days and another at eighty-four days, the first from hemorrhages in the lungs, the second as the result of an impacted cecum. The scurvy scores for the entire year for the animals receiving 30 cc. of milk varied from 4 to 15, with an average score of 9. In most cases, the animals which had high scurvy scores lost weight beginning with the onset of scurvy at the seventieth to the eightieth day.

For animals fed 40 cc. of milk daily, the average score for the year was 3. The scurvy scores for these animals varied from no score to 7. In most cases the scurvy symptoms were scarcely perceptible in the animals receiving 40 cc. of milk daily when they were alive, but were easily seen on autopsy. A large number of the animals in the group receiving 40 cc. of milk had diseased lungs. The lung trouble first occurred among the animals in January, 1926, and from then on was prevalent among the experimental animals used. All the animals took their full allowances of milk every day in spite of the lung trouble.

Fewer animals were fed 50 cc. of milk daily than 30 or 40 cc., because of the difficulty in feeding and the tendency to digestive disturbances among animals receiving the larger amounts of milk. As was stated earlier, the two animals which received 50 cc. of milk daily in the summer and fall of 1925 were healthy and showed no trace of scurvy on autopsy. Unfortunately, all but one of the remaining animals which received 50 cc. of milk daily showed diseased lungs at autopsy. Only one of these had any signs of scurvy. It died at seventy-nine days and had a diseased liver as well as infected lungs.

In table 2, all the animals receiving 30, 40 and 50 cc. of milk daily have been grouped by seasons. By means of the scurvy score of each animal, the percentage of complete protection afforded by the milk fed has been calculated and the number of cubic centimeters necessary for complete protection has been found. An average of the results obtained on thirty-eight animals tested at all seasons of the year gave 49 cc. as the amount of milk per animal daily necessary for complete protection. This average includes eight animals which were fed 50 cc. of milk daily and were fully protected by this amount. The amounts required for the complete protection of these animals were probably under 50 cc.

The average figure for complete protection for the summer of 1925 was 52 cc. For the fall of 1925, the average number of cubic centimeters of milk required for complete protection by the eight animals in the group was found to be 48 cc. For the winter of 1926, the figure for twelve animals was 51 cc., and for the spring the figure for fifteen animals was 46 cc. Significant differences could not be found to exist, therefore, between the amounts of milk (52, 48, 51 and 46 cc.) required by the animals at different times of the year.

The average of 49 cc. found for the year is strikingly lower than the 80 cc. quoted by Hess and Unger[6] and the from 85 to 130 cc. found by Chick, Hume and Skelton[2] to be the amounts necessary for the complete protection of a guinea-pig from scurvy. The high antiscorbutic potency of this milk is undoubtedly due to the good quality of the ensilage fed to the cows, although it has been reported by Ellis, Steenbock and Hart[14] that ensilage and sauerkraut are both of low antiscorbutic value. In this connection it is interesting to note that sauerkraut, which is similar to ensilage, was considered to be of value as an antiscorbutic more than a century ago, for according to Hess[15] it was kept on hand by "the famous navigator Cook, whose voyages were remarkable for the freedom from illness which his sailors enjoyed and the absence of scurvy."

CONCLUSIONS

It can be safely concluded from this investigation that 50 cc. of the milk used in these experiments, fed six days a week, is sufficient to protect a 300 Gm. guinea-pig from scurvy at any time of the year. As a result of this work it can be concluded also that the milk of stall-fed cows which are given a well balanced, uniform diet throughout the year will not show seasonal variation in its antiscorbutic value. By including an ensilage of good quality in the ration, the antiscorbutic potency of the milk may be maintained at a high level.

TABLE 2.—*Milk Required at Different Seasons for Protection from Scurvy (Experimental Period, Ninety days)*

Season	Number of Animals	Amount of Milk Fed, Cc.	Average Scurvy Score at Autopsy	Degree of Scurvy	Milk Necessary for Protection, Calculated, Cc.
Summer..........	1	30	11	Severe	55
	2	50	0	None	50
					Av. = 52 cc.
Fall..............	4	30	8.4	Moderate	48
	4	40	4.1	Mild	49
					Av. = 48 cc.
Winter...........	3	30	9.8	Moderate	54
	5	40	4.0	Mild	48
	4	50	0.9	Slight	52
					Av. = 51 cc.
Spring............	5	30	7.4	Moderate	44
	7	40	2.5	Mild	45
	3	50	0	None	50
					Av. = 46 cc.

Hess estimates that an infant requires five times as much vitamin C as a guinea-pig for protection against scurvy. On the basis of this estimate and these experimental results, it would seem safe to conclude that raw milk from cows fed as described will furnish sufficient antiscorbutic vitamin to protect an infant from scurvy.

THE VITAL CAPACITY OF THE NEGRO CHILD

FRANK L. ROBERTS, M.D.
AND
JAMES A. CRABTREE, M.D.
State Field Directors, Tennessee State Department of Public Health
TRENTON, TENN.

The purpose of this study is to ascertain the vital capacity of a group of normal negro children and compare these vital capacities with those of a group of white children living in the same territory. The negro child forms an integral part of our population and must be considered in any health program. It has been shown that negro children are heavier than white children of the same age and height,[1] and in many other ways the negro physical standard differs from that of the white. For this reason, therefore, it was thought advisable to determine the vital capacity of these children.

In a careful review of the literature but little was found dealing with the vital capacity of negroes. Wilson and Edwards[2] measured thirty-eight normal colored children, and stated that these children had vital capacities definitely lower than white children. Dr. W. G. Smillie of the International Health Board stated[3] that he and Dr. Augustine had measured the vital capacity of negro children in Alabama and found that they had vital capacities definitely lower than white children; the same results were obtained on adults. Foster[4] states that the Chinese have vital capacities lower than westerners. As far as we could learn, these few studies are all that have been made on races other than the white.

MATERIALS AND METHODS

This study is based on observations on 1,564 white children and 1,254 negro children. The children are from rural and urban localities, and form more than 25 per cent of the total school population of the county. This number is therefore an adequate sample of the child population. The children were grouped according to sex. The standing height in centimeters, the weight in pounds, the stem length and the age were ascertained. A Sanborn wet spirometer was used, and the measurements were taken as described in a former paper.[5] Edwards and Wilson[6] have shown that the Sanborn spirometer agrees very closely with their specially constructed instrument.

The average vital capacity, the standard deviation, the coefficient of variation, the probable error of the mean and the probable error of the difference were calculated for each group. The standard deviation was calculated by the formula $SD=\sqrt{\frac{Sd^2}{N}}$, in which SD equals the standard deviation, Sd^2 the sum of the squares of the individual deviations, and N the number of cases. The probable error of the mean was calculated by the formula $PE=0.674494\frac{SD}{\sqrt{N}}$, in which SD is the standard deviation and N the number of cases. The probable error of the difference between the vital capacity of the whites and the negroes was ascertained by the equation $PE_{x-y}=\sqrt{PE^2_x+PE^2_y}$, in which PE_x is the probable error of the mean vital capacity of the white children and PE_y is the probable error of the mean for the negro children.

VITAL CAPACITY AND AGE

The vital capacities are tabulated with reference to age. Chart 1 shows these data in graphic form. In children of 6 years and under the vital capacity readings are not satisfactory, for the reason that it is difficult to secure the cooperation of the child. It has been shown by many workers that age is not a very satisfactory index for vital capacity, but it does bring out some significant facts.

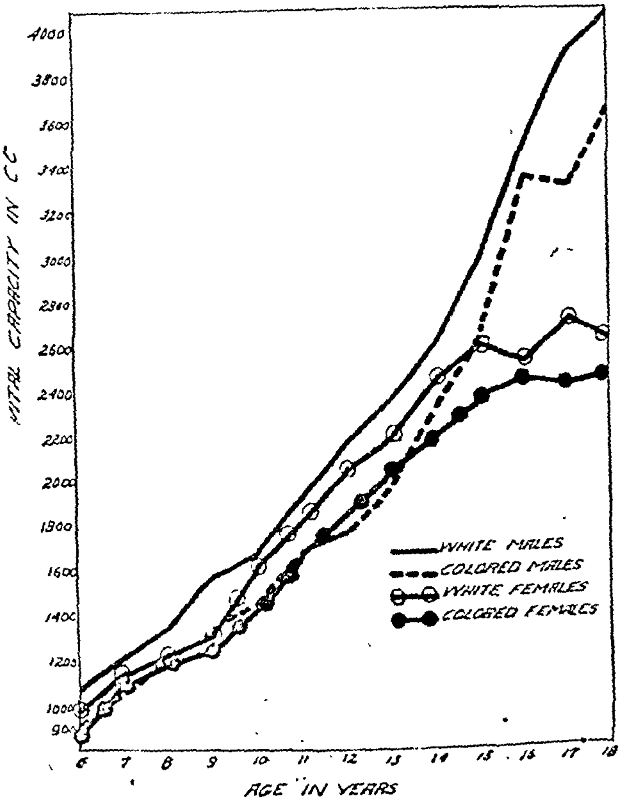

Chart 1.—Relation between age and vital capacity by sex and color.

As will be noticed, the vital capacities of the white boys exceed those of the white girls. This has been demonstrated before. In the case of the colored children this difference is not so marked. The average annual increase in the vital capacity of white boys is 168 cc. up to 13 years of age; from 13 to 18 this increase is 360 cc. The curve shows this acceleration in vital capacity after the thirteenth year. For the colored boys the annual increase is 154 cc. up to 13 years, and 334 cc. thereafter. These increases in the two races agree very closely, and the similarity is shown in the curves.

For the white girls the average annual increase from 6 to 9 years was 137 cc. From 9 to 12 the increase was 236 cc.; from 12 to 15 years, 187 cc., and from

[6] Edwards, D. J., and Wilson, May G.: An Analysis of Some of the Factors of Variability in the Vital Capacity Measurement of Children, Arch. Int. Med. **30**: 638-647 (Nov.) 1922.

15 to 18 years it was not increased. In short, there were four phases: a rather slow increase up to 9 years; from 9 to 12 years an acceleration in the vital capacity; from 12 to 15 years a lessened acceleration, and from 15 years onward a tendency for the curve to straighten out.

For the negro girls the average increase is 120 cc. yearly from 6 to 9 years; 194 cc. from 9 to 12 years; 215 cc. from 12 to 15 years, and from 15 to 18 years the curve flattens. This agrees very closely with the curve for the white girls, except that the greatest acceleration is in the third phase instead of the second.

The coefficient of variation was slightly more in the white children than in the negroes. The average coefficient of variation for the white girls was 19.8 per cent and for the negro girls 17.7 per cent. For the white boys the coefficient of variation was 18.4, and for the negro boys 17.5 per cent.

It is evident that there is a marked difference in the vital capacity of the negro and the white. With the boys this difference is four or more times its probable error in every case except the 16 year group. When a difference is four or more times its probable error, it is almost certainly significant. The white girls exceed the colored girls in every case, but only in the 10, 11, 12, 14, 15 and 17 year age groups is the difference significant. We cannot explain why the difference is less marked in the girls than in the boys; it may be due to chance.

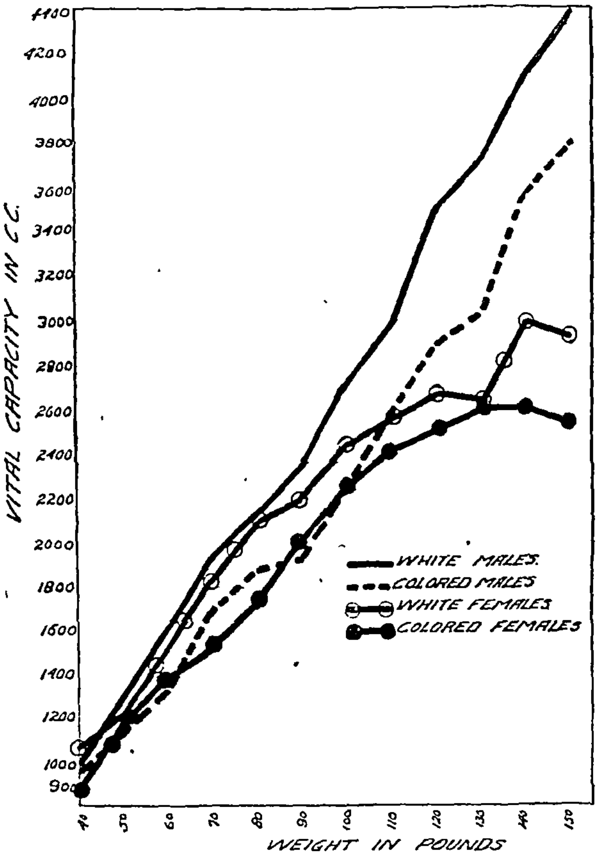

Chart 2.—Relation between body weight and vital capacity by sex and color.

Calculating the difference on a percentage basis reveals that the average difference in the vital capacity of the white girls and the negro girls is 7.2 per cent in favor of the white girls, and that the white boys have capacities averaging 12 per cent more than those of negro boys of the same age.

VITAL CAPACITY AND BODY WEIGHT

Body weight is a much better index for vital capacity than is age. For every 10 pounds (4.5 Kg.) increase in the body weight of white girls examined, there was a corresponding average increase of 171 cc. in vital capacity. The increase seems to be uniform up to 150 pounds (68 Kg.), and thereafter the curve tends to flatten. For each 10 pound increase in body weight of colored girls there is an increase of 156 cc. in vital capacity up to 130 pounds (59 Kg.). After 130 pounds there is practically no increase in vital capacity.

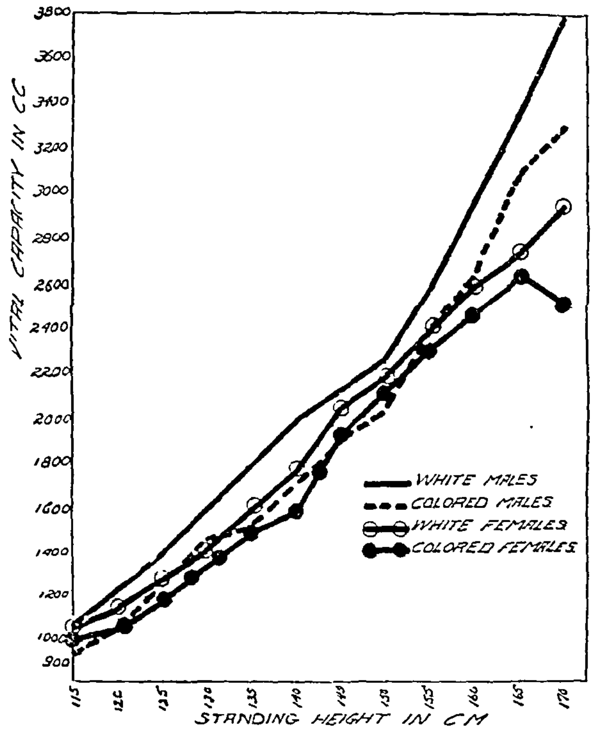

Chart 3.—Relation between standing height and vital capacity by sex and color.

The vital capacity of the colored boys increases 254 cc. with every 10 pound increase in body weight. From 40 to 80 pounds (18 to 36 Kg.), the average increase is 248 cc. From 80 to 130 pounds (36 to 59 Kg.) there is a slight acceleration, the average increase being 255 cc. From 130 to 150 pounds (59 to 68 Kg.) the increase is 294 cc. The white boys show an increase of 309 cc. in vital capacity with each 10 pound increase in body weight. This increase is not uniform, as there are three phases in the curve. From 40 to 80 pounds the average increase is 315 cc. From 80 to 110 pounds (36 to 50 Kg.) the increase is 259 cc., and from this point on there is an acceleration with an average increase in vital capacity of 334 cc.

As shown in chart 2, the white children have greater vital capacity weight for weight than do the negroes. The white boys exceed the colored boys by an average of 14.9 per cent, while the colored girls are 10.2 per cent below the white girls. In the case of the boys, the difference is almost certainly significant in every group except the 40 pound group, and the difference between the white and the negro girls is significant in every case except the 130 pound group.

VITAL CAPACITY AND STANDING HEIGHT

For each 5 cm. increase in standing height the white girls show an average absolute increase of 139 cc. in vital capacity up to 140 cm. After 140 cm. there is a slight acceleration, and the average absolute increase is 194 cc. The colored girls gain 111 cc. in vital capacity for each 5 cm. increase in standing height up to 140 cm., and they gain 170 cc. for each increase thereafter.

In the boys the acceleration is much more marked after 150 cm. In the white boys the average absolute increase in vital capacity is 167 cc. up to 150 cm. in standing height, and 386 cc. thereafter. The negro boys show an average absolute increase in vital capacity of 155 cc. up to 150 cm., and 311 cc. thereafter. The charts show the similarity between the increase of both girls and boys.

The difference in the vital capacity of the two races is shown better in the boys than in the girls. In seven out of ten groups of boys, the difference is almost certainly significant. In only two out of ten cases is the difference significant in the female group. However, the white girls in every case have vital capacities greater than the colored girls. The white boys average 11.2 per cent higher than colored boys with regard to vital capacity, and the white girls exceed the colored girls by 6.8 per cent.

In the standing height group there is practically no difference in the coefficient of variation. The white boys average 14.9 per cent and the colored boys 15.6 per cent, and the white girls and colored girls show a coefficient of variation of 16.3 and 16.5 per cent, respectively.

VITAL CAPACITY AND SITTING HEIGHT

When the vital capacities of negro children are compared with those of white children on the basis of sitting height, we find that there is no significant difference. In only five out of twelve groups do the white girls exceed the negro girls, and not one of the differences is significant. In seven out of twelve groups the negro girls exceed the white girls. In six out of twelve groups the white boys have vital capacities slightly greater than those of the negro boys, and in the other six cases the negro boys exceed the white boys.

For each 2 cm. increase in stem length the white boys gain 171 cc. in vital capacity up to 79 cm.; at this point there is an acceleration, and the increase from 79 cm. to 85 cm. amounts to 253 cc. for each 2 cm. group. The negro boys show an increase of 139 cc. in vital capacity for each 2 cm., an increase in stem length up to 75 cm., and from there on the increase is 296 cc.

The white girls show a fairly uniform average increase of 151 cc. in vital capacity for each 2 cm. increase in stem length. The negro girls show an average increase of 133 cc. in vital capacity up to 73 cm. in stem length. After 73 cm. there seems to be a slight acceleration of the negro girls, as they show an average increase of 152 cc. in vital capacity for each 2 cm. increase in stem length.

The coefficient of variation is practically the same for negro children and white children, the average being 16.5 per cent for the white girls, 16.8 per cent for the negro girls, and 14.4 and 15.8 per cent for the white and negro boys, respectively.

SUMMARY AND CONCLUSIONS

We found in our study of the vital capacities of negro children that they are definitely lower than those of the white children of the same age, body weight, and standing height. The difference is not so marked as in the groups studied by Smillie and Augustine, but is a marked and significant difference. We noted in nearly every group of white children studied by us that the vital capacities were lower than those recorded by Smillie and Augustine. This will probably account for the smaller differences in our group. We did not find a significant difference in the vital capacities of the negro children and white children on the basis of stem length.

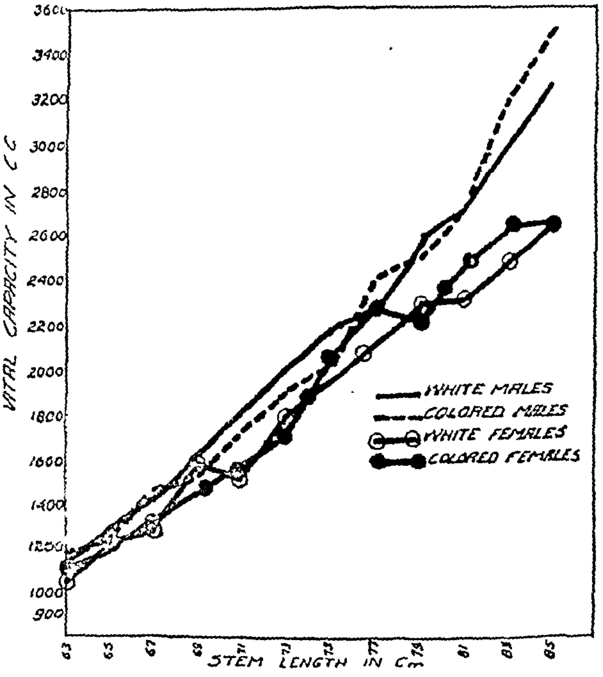

Chart 4.—Relation between stem length and vital capacity by sex and color.

Our conclusions may be summarized thus:

1. The negro children have vital capacities lower than white children of the same age. The difference is greater in the case of the boys. White girls exceed negro girls by 7.2 per cent, and white boys exceed the colored by 12 per cent in vital capacity.
2. Negro children have vital capacities lower than white children of the same body weight. The white girls exceed the colored girls by 10.2 per cent, and the white boys exceed the negro boys by 14.9 per cent in lung capacity.
3. Negro children have vital capacities lower than white children of the same standing height. The white girls show vital capacities averaging 6.8 per cent higher than negro girls, and the white boys have vital capacities that average 11.2 per cent higher than those of negro boys.
4. Negro children have vital capacities practically the same as those of white children of the same stem length.

DISTURBED SURFACE AREA PROPORTIONS IN A CASE OF SUSPECTED OVARIAN HYPERFUNCTION *

SAMUEL GORDON BERKOW, M.D.
PERTH AMBOY, N. J.

A previous report[1] demonstrated that the surface area proportions of the head, trunk, upper extremities and lower extremities are nearly constant in adults, and that in infants and children the proportions of these parts are different, varying with age until, gradually, adult proportions are assumed. The head, it was demonstrated, decreased from 18 per cent of the total area at birth to 6 per cent in the adult; the lower extremities increased from 25 per cent at birth to 38 per cent in the adult. The trunk and upper extremities varied less progressively. The extremes of variation from the average proportions of seventeen adults of various physical conformation were: head, + 0.8 and — 0.4; upper extremities, + 1 and — 2.9; trunk, + 6 and — 2.3, and lower extremities, + 2 and — 4.2.

The component parts of the upper extremities were: arms, 26 per cent; hands, 73 per cent; lower extremities: thighs, 50 per cent; legs, 32 per cent, and feet, 17 per cent. These varied little in individuals of different physique.

A further study of the proportions in children was made in the Perth Amboy public schools, with the cooperation of Mazie Traimen Berse, then in charge of the mentally defective classes. The children measured were of widely different mental and physical types. Attempts to establish a normal average for each age were not made, the number of children that could be measured being small, and the explicit approval of the school authorities not having been obtained. In this manner, thirty-two children were measured, bringing the total with the children previously measured to fifty-six. The proportions were found to be practically constant for each age, regardless of stature, nutritional state or mental age. We found that, given the age of the child, we could always state the ratio of the head to the total surface within 1 per cent of what actual measurements and calculation would reveal, and the proportions of the other parts could be stated with somewhat less exactitude.

The proportions of the component parts of the upper and lower extremities were found not to vary with age, being essentially the same in the infant and adult. They were found to be particularly constant in all the persons measured.

It is interesting to observe that nutritional disturbances, such as rickets, influenced surface area proportions very slightly.

It was also noted previously that "B. L., a cretin, 36 years old, measured by Delafield and Eugene Du Bois,[2] and reported by them to have the general mental and physical development of a boy of 8, had the proportions found at 8 years of age, except for the upper extremities. Whether disproportions of various kinds typify different forms of endocrine imbalance is a problem which at once suggests itself."

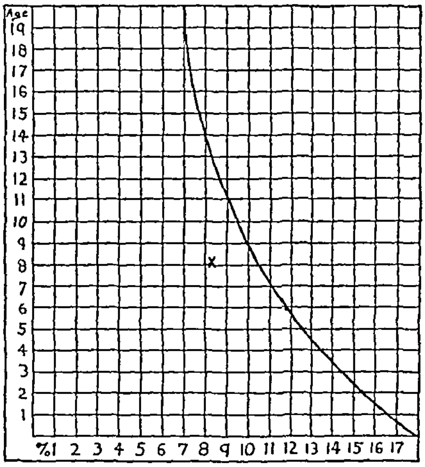
The present report concerns a case of suspected ovarian disturbance in a child, aged 8 years, in whom the surface area of the head represents a different proportion of the total body surface from what has been observed in any other child of that age.

REPORT OF CASE

F. S., a girl, born Oct. 5, 1918, was admitted, Oct. 18, 1926, to the pediatric clinic at Post-Graduate Medical School and Hospital. The mother complained that the child had been bleeding vaginally for six months, a few spots of blood being observed on the child's drawers every day. The bleeding was not periodic, although the mother stated that the amount of hemorrhage varied, never being profuse. Recently, the bleeding had been slightly augmented in volume. Other complaints were not present, the child being otherwise in good health. She was well up in her grade at school. A painstaking inquiry did not elicit a history of masturbation. Physical examination (made by Drs. Bergman and Kurzweil) was negative, except for a protuberant abdomen. Masses were not felt in the abdomen.

The child weighed 73½ pounds (33.4 Kg.) and was 51 inches (129.5 cm.) tall. The temperature was 98 F.; the pulse, 104, and the respiration, 22. She was well nourished.

She was referred to the gynecology clinic of Professor West for further examination. Pelvic examination by Dr. Conterno, Dr. Robertiello and myself of that clinic, and by Dr. Moench and Dr. Church of Professor Furniss' clinic, revealed the hymen intact, but the vaginal orifice admitted the tip of the fifth finger; rectal examination was negative except for a slight enlargement of the uterus. A cotton-wrapped applicator introduced into the vagina was found on withdrawal to be blood-tinged.



Curve representing proportion between head and total surface area in children. The percentage area of the head of the patient is marked by a cross.

On the basis of these observations, largely negative, a diagnosis of ovarian hyperfunction was made, Dr. Kurzweil of the pediatric department disagreeing. I then measured the child according to the linear method of Delafield and Eugene Du Bois,[2] and the proportions of the head, trunk, upper extremities (arms and hands) and lower extremities (feet, legs and thighs) were computed from these measurements. The measurements were: head, 8.5 per cent; trunk, 38.7 per cent; upper extremities, 16.7 per cent; lower extremities, 35.9 per cent.

COMMENT

These data differ materially from the average for the age group only in the proportion of the head, which is fully 2 per cent less than the ratio between that part and the total surface in other children 8 years old. This is nearly twice the variation encountered heretofore in the most divergent cases in one age group. The difference is in favor of the adult type. The accompanying chart gives the curve of head proportions from

except the 40 pound group, and the difference between the white and the negro girls is significant in every case except the 130 pound group.

VITAL CAPACITY AND STANDING HEIGHT

For each 5 cm. increase in standing height the white girls show an average absolute increase of 139 cc. in vital capacity up to 140 cm. After 140 cm. there is a slight acceleration, and the average absolute increase is 194 cc. The colored girls gain 111 cc. in vital capacity for each 5 cm. increase in standing height up to 140 cm., and they gain 170 cc. for each increase thereafter.

In the boys the acceleration is much more marked after 150 cm. In the white boys the average absolute increase in vital capacity is 167 cc. up to 150 cm. in standing height, and 386 cc. thereafter. The negro boys show an average absolute increase in vital capacity of 155 cc. up to 150 cm., and 311 cc. thereafter. The charts show the similarity between the increase of both girls and boys.

The difference in the vital capacity of the two races is shown better in the boys than in the girls. In seven out of ten groups of boys, the difference is almost certainly significant. In only two out of ten cases is the difference significant in the female group. However, the white girls in every case have vital capacities greater than the colored girls. The white boys average 11.2 per cent higher than colored boys with regard to vital capacity, and the white girls exceed the colored girls by 6.8 per cent.

In the standing height group there is practically no difference in the coefficient of variation. The white boys average 14.9 per cent and the colored boys 15.6 per cent, and the white girls and colored girls show a coefficient of variation of 16.3 and 16.5 per cent, respectively.

VITAL CAPACITY AND SITTING HEIGHT

When the vital capacities of negro children are compared with those of white children on the basis of sitting height, we find that there is no significant difference. In only five out of twelve groups do the white girls exceed the negro girls, and not one of the differences is significant. In seven out of twelve groups the negro girls exceed the white girls. In six out of twelve groups the white boys have vital capacities slightly greater than those of the negro boys, and in the other six cases the negro boys exceed the white boys.

For each 2 cm. increase in stem length the white boys gain 171 cc. in vital capacity up to 79 cm.; at this point there is an acceleration, and the increase from 79 cm. to 85 cm. amounts to 253 cc. for each 2 cm. group. The negro boys show an increase of 139 cc. in vital capacity for each 2 cm., an increase in stem length up to 75 cm., and from there on the increase is 296 cc.

The white girls show a fairly uniform average increase of 151 cc. in vital capacity for each 2 cm. increase in stem length. The negro girls show an average increase of 133 cc. in vital capacity up to 73 cm. in stem length. After 73 cm. there seems to be a slight acceleration of the negro girls, as they show an average increase of 152 cc. in vital capacity for each 2 cm. increase in stem length.

The coefficient of variation is practically the same for negro children and white children, the average being 16.5 per cent for the white girls, 16.8 per cent for the negro girls, and 14.4 and 15.8 per cent for the white and negro boys, respectively.

SUMMARY AND CONCLUSIONS

We found in our study of the vital capacities of negro children that they are definitely lower than those of the white children of the same age, body weight, and standing height. The difference is not so marked as in the groups studied by Smillie and Augustine, but is a marked and significant difference. We noted in nearly every group of white children studied by us that the vital capacities were lower than those recorded by Smillie and Augustine. This will probably account for the smaller differences in our group. We did not find a significant difference in the vital capacities of the negro children and white children on the basis of stem length.

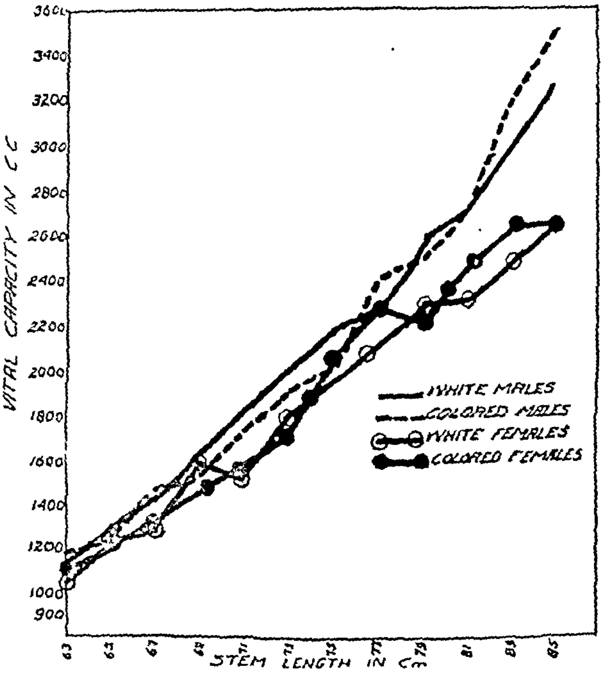

Chart 4.—Relation between stem length and vital capacity by sex and color.

Our conclusions may be summarized thus:

1. The negro children have vital capacities lower than white children of the same age. The difference is greater in the case of the boys. White girls exceed negro girls by 7.2 per cent, and white boys exceed the colored by 12 per cent in vital capacity.
2. Negro children have vital capacities lower than white children of the same body weight. The white girls exceed the colored girls by 10.2 per cent, and the white boys exceed the negro boys by 14.9 per cent in lung capacity.
3. Negro children have vital capacities lower than white children of the same standing height. The white girls show vital capacities averaging 6.8 per cent higher than negro girls, and the white boys have vital capacities that average 11.2 per cent higher than those of negro boys.
4. Negro children have vital capacities practically the same as those of white children of the same stem length.

DISTURBED SURFACE AREA PROPORTIONS IN A CASE OF SUSPECTED OVARIAN HYPERFUNCTION *

SAMUEL GORDON BERKOW, M.D.
PERTH AMBOY, N. J.

A previous report[1] demonstrated that the surface area proportions of the head, trunk, upper extremities and lower extremities are nearly constant in adults, and that in infants and children the proportions of these parts are different, varying with age until, gradually, adult proportions are assumed. The head, it was demonstrated, decreased from 18 per cent of the total area at birth to 6 per cent in the adult; the lower extremities increased from 25 per cent at birth to 38 per cent in the adult. The trunk and upper extremities varied less progressively. The extremes of variation from the average proportions of seventeen adults of various physical conformation were: head, + 0.8 and — 0.4; upper extremities, + 1 and — 2.9; trunk, + 6 and — 2.3, and lower extremities, + 2 and — 4.2.

The component parts of the upper extremities were: arms, 26 per cent; hands, 73 per cent; lower extremities: thighs, 50 per cent; legs, 32 per cent, and feet, 17 per cent. These varied little in individuals of different physique.

A further study of the proportions in children was made in the Perth Amboy public schools, with the cooperation of Mazie Traimen Berse, then in charge of the mentally defective classes. The children measured were of widely different mental and physical types. Attempts to establish a normal average for each age were not made, the number of children that could be measured being small, and the explicit approval of the school authorities not having been obtained. In this manner, thirty-two children were measured, bringing the total with the children previously measured to fifty-six. The proportions were found to be practically constant for each age, regardless of stature, nutritional state or mental age. We found that, given the age of the child, we could always state the ratio of the head to the total surface within 1 per cent of what actual measurements and calculation would reveal, and the proportions of the other parts could be stated with somewhat less exactitude.

The proportions of the component parts of the upper and lower extremities were found not to vary with age, being essentially the same in the infant and adult. They were found to be particularly constant in all the persons measured.

It is interesting to observe that nutritional disturbances, such as rickets, influenced surface area proportions very slightly.

It was also noted previously that "B. L., a cretin, 36 years old, measured by Delafield and Eugene Du Bois,[2] and reported by them to have the general mental and physical development of a boy of 8, had the proportions found at 8 years of age, except for the upper extremities. Whether disproportions of various kinds typify different forms of endocrine imbalance is a problem which at once suggests itself."

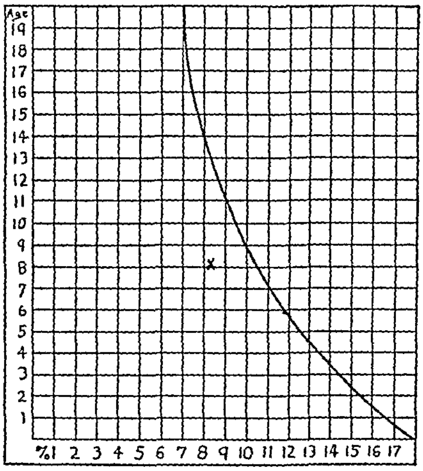
The present report concerns a case of suspected ovarian disturbance in a child, aged 8 years, in whom the surface area of the head represents a different proportion of the total body surface from what has been observed in any other child of that age.

REPORT OF CASE

F. S., a girl, born Oct. 5, 1918, was admitted, Oct. 18, 1926, to the pediatric clinic at Post-Graduate Medical School and Hospital. The mother complained that the child had been bleeding vaginally for six months, a few spots of blood being observed on the child's drawers every day. The bleeding was not periodic, although the mother stated that the amount of hemorrhage varied, never being profuse. Recently, the bleeding had been slightly augmented in volume. Other complaints were not present, the child being otherwise in good health. She was well up in her grade at school. A painstaking inquiry did not elicit a history of masturbation. Physical examination (made by Drs. Bergman and Kurzweil) was negative, except for a protuberant abdomen. Masses were not felt in the abdomen.

The child weighed 73½ pounds (33.4 Kg.) and was 51 inches (129.5 cm.) tall. The temperature was 98 F.; the pulse, 104, and the respiration, 22. She was well nourished.

She was referred to the gynecology clinic of Professor West for further examination. Pelvic examination by Dr. Conterno, Dr. Robertiello and myself of that clinic, and by Dr. Moench and Dr. Church of Professor Furniss' clinic, revealed the hymen intact, but the vaginal orifice admitted the tip of the fifth finger; rectal examination was negative except for a slight enlargement of the uterus. A cotton-wrapped applicator introduced into the vagina was found on withdrawal to be blood-tinged.



Curve representing proportion between head and total surface area in children. The percentage area of the head of the patient is marked by a cross.

On the basis of these observations, largely negative, a diagnosis of ovarian hyperfunction was made, Dr. Kurzweil of the pediatric department disagreeing. I then measured the child according to the linear method of Delafield and Eugene Du Bois,[2] and the proportions of the head, trunk, upper extremities (arms and hands) and lower extremities (feet, legs and thighs) were computed from these measurements. The measurements were: head, 8.5 per cent; trunk, 38.7 per cent; upper extremities, 16.7 per cent; lower extremities, 35.9 per cent.

COMMENT

These data differ materially from the average for the age group only in the proportion of the head, which is fully 2 per cent less than the ratio between that part and the total surface in other children 8 years old. This is nearly twice the variation encountered heretofore in the most divergent cases in one age group. The difference is in favor of the adult type. The accompanying chart gives the curve of head proportions from

[1] Berkow, S. G.: A Method of Estimating the Extensiveness of Lesions (Burns and Scalds) Based on Surface Area Proportions, Arch. Surg. 8: 138 (Jan.) 1924.

[2] Du Bois, Delafield; and Du Bois, E. F.: The Measurements of the Surface Area of Man, Arch. Int. Med. 15: 868 (May) 1915.

infancy to 20 years and marks the relative position of the head in this case.

The remaining proportions are within the usual limits. The components of the upper and lower extremities exhibit the usual ratios. The arms are 72.2 per cent; hands, 27.7 per cent of the upper extremities; the thighs are 50.6 per cent; the legs, 30.7 per cent, and the feet 18.6 per cent of the lower extremities.

The assumption of an abnormal disproportion of the head in this child does not warrant the conclusion that this abnormality can be linked with the symptoms complained of. However, it does seem significant that the greatest disparity in proportions has been observed in a case of known endocrine disturbance (the cretin) and in a case of suspected imbalance. It serves to strengthen the hypothesis, supported by the known influence of these glands on growth, that a mathematical index of endocrine imbalance may be derived from a further study of proportions.

TUBERCULOSIS AND GOITER*

E. P. SLOAN, M.D.
BLOOMINGTON, ILL.

All authorities are agreed on the difficulties sometimes encountered in making a differential diagnosis between pulmonary tuberculosis in the incipient or minimal stage (without definite lung signs) and early goiter when not accompanied by appreciable enlargement of the thyroid. All are agreed on the striking similarity in the symptom complex of the two conditions. In both goiter and early tuberculosis there are tachycardia, instability of the pulse, progressive loss of weight, sweating, nervous symptoms and emotional changes. As regards the metabolic rate as a means of differentiation, in some cases of tuberculosis there is a slight increase in metabolic rate almost identical with that so often seen in the forme fruste or mild type of exophthalmic goiter. Consequently, this criterion also fails us in the differentiation of these two conditions.

In both conditions are found sympathetic disturbance and loss of weight despite increased appetite. If to the foregoing syndrome there is added the appearance of a mild or moderate thyroid enlargement, especially in the female during puberty or pregnancy, a diagnostic problem is presented that sometimes will baffle the most acute observer. The symptoms of the two conditions are often similar; indeed, almost identical. One is inclined to think that in many cases they actually are identical: in other words, that both are present. Many are inclined to believe nowadays that the exciting cause of exophthalmic goiter, in the great majority of cases, is infection. If this is so, one can hardly conceive of normal thyroid function in the presence of the long drawn out toxemia of tuberculosis. A toxemic dysfunction of the thyroid will explain many of the symptoms of atypical tuberculosis.

THYROID CHANGES IN PULMONARY TUBERCULOSIS (?) AND THEIR CORRELATION WITH SYMPTOMS

Is there any pathologic basis for a theory of thyroid dysfunction in tuberculosis? Unfortunately, the subject of thyroid disease in tuberculosis has not received the attention its importance demands. Reports of very few thyroidectomies done in the early stages of tuberculosis have been published; consequently very little information as to the pathologic changes in the gland at this time is available. This fact is of great significance, as it is precisely in the early stages of tuberculosis that there are most often marked symptoms of thyroid dysfunction. There is, however, a wealth of autopsy statistics relative to patients dead of tuberculosis, and, according to these statistics, sclerosis of the thyroid is very common in advanced tuberculosis. Now, it is a frequent clinical observation that as the tuberculosis advances the symptoms suggestive of thyroid disturbance show some tendency to improve.

Correlation of these two facts leads to the formulation of an inviting hypothesis as to the changes that actually take place in the thyroid gland. The sclerosis found in the advanced case is, of necessity, a secondary or late stage of inflammation. Antedating the sclerosis one may presuppose toxemic stimulation and inflammatory change, and inflammatory change in thyroid tissue is, in my opinion, always attended with symptoms of thyroid dysfunction.

ACTIVE TUBERCULOUS LESIONS OF THE THYROID

The thyroid apparently does possess some degree of immunity against actual bacillary invasion and the resulting destructive or fibrotic change.

The idea that, in the majority of cases, the sclerosis and antecedent hyperplasia are due to toxemia rather than to bacillary invasion finds definite support in the fact that sclerosis of the thyroid has been found in the new-born children of tuberculous mothers. Even without the aid of statistics, it would perhaps be reasonable to conclude that in a structure as vascular as the thyroid, chronic caseous tuberculosis must of necessity be rare.

Tuberculous lesions, however, do occur. Last December, in Detroit, I was furnished two patients for demonstration in a diagnostic goiter clinic on whom thyroidectomies had been done within the last year. Both patients were in rather advanced stages of pulmonary tuberculosis. Removal revealed tubercles disseminated throughout both glands. Tubercle bacilli were present not only within the tubercles that were visible macroscopically but also in other portions of the gland. Both patients following thyroidectomy were greatly improved and are carrying their active pulmonary tuberculosis with progressive appreciable improvement in their condition.

Tubercles in the thyroid are common in cases of miliary tuberculosis; Weigert examined the thyroid in eleven cases of miliary tuberculosis and found tubercles in every case. Lesions of chronic tuberculosis are also found. Chiari found tuberculous lesions in the thyroid in 7 per cent of a series of autopsies in cases of pulmonary tuberculosis. Fraenkel found lesions in six of fifty cases examined. Depending on their extent and the degree of secondary inflammatory changes in the gland, these lesions may, of course, cause symptoms of goiter.

IODINE CONTENT OF THE THYROID IN TUBERCULOSIS

Unfortunately, sufficient work along this line has not been done. Gautier, however, found the iodine decreased or absent. I have, in addition, an interesting observation to offer. Years ago some of the supposedly early cases of tuberculosis showed a distinct improvement, especially lowered pulse rate, consequent on the use of the crude cod liver oil then obtainable. I believe now that the improvement, which was then attributed to the nutritive qualities of the oil, was in reality often due to the iodine and other mineral salts which it contained, and that a percentage of the cases that improved on this treatment were really cases of atypical exophthalmic goiter rather than tuberculosis. I have not noted the same improvement in similar cases consequent on the administration of the refined cod liver oil of recent years. The reason for this, I think, may be that in the refining process the mineral content, especially the iodine content, of the oil is appreciably lessened.

---

* Read before the Chicago Tuberculosis Society, March 10, 1927.

THREE TYPES OF DIAGNOSTIC PROBLEM IN EARLY CASES

In the differential diagnosis of early tuberculosis and exophthalmic goiter, there are three possibilities to be considered:

1. The incipient case of tuberculosis, without demonstrable lung lesion, resembling mild exophthalmic goiter.
2. The forme fruste or mild type of exophthalmic goiter resembling early tuberculosis.
3. Coexistent tuberculosis and goiter.

Rest is fortunately the essential element in the treatment of all these conditions, and it is possible that some cases of forme fruste exophthalmic goiter, after a rest of from three to six months in sanatoriums, are considered "arrested cases" of pulmonary tuberculosis and the patient is discharged. It is possible that some in the third group, patients having both *mild* tuberculosis and mild goiter, are discharged as having arrested tuberculosis; and rightly, too, as the tuberculosis is arrested, though the thyroid is still active or toxic. These patients have a pulse rate higher than is consistent with the temperature curve.

The diagnosis, of course, is most important, and with patience can be made in most cases. Too much reliance is being placed on so-called specific tests and complicated laboratory procedure. The Goetsch test and the tuberculin test point the wrong road perhaps more often than they point the right road. For the differentiation of these confusing syndromes, clinical judgment and experience are much more important than refined laboratory technic. We should bear in mind in considering these and similar conditions the famous dictum of John B. Murphy, "Diagnoses are made with cortical cells rather than with instruments of precision." An early diagnosis may save the patient years of anxiety and invalidism and much needless expense incurred in sanatorium care and perhaps climatic wanderings.

COEXISTENT TUBERCULOSIS AND GOITER

Incidence.—Fishberg of New York says, "It is well known that quite a large proportion of the tuberculous patients present signs of hyperthyroidism, such as more or less bulging eyes, tachycardia, slight tremor, hot flashes, sweating, dermographism and even enlargement of the thyroid gland."

In fifty cases of exophthalmic goiter seen by Saathoff, evidence of mild tuberculosis was found in forty-eight. The two remaining cases were more advanced and showed bacilli in the sputum. Caro examined 486 men of the thyroid diathesis, and found evidence of apical trouble in 210. Schinzinger, in a group of 521 tuberculous patients, discovered signs and symptoms in 191 that suggested very strongly the coexistence of exophthalmic goiter. Many other writers quote a goiter incidence of from 4 to 8 or 10 per cent among their tuberculous patients. These figures show that the coexistence of goiter and pulmonary tuberculosis is not, by any means, a rare condition.

This opinion as to the rather frequent coexistence of the two conditions is not shared by all authorities. In one of the recent books on goiter, the statement is made that the author had never seen a case of coexisting goiter and tuberculosis. A few years ago the superintendent of a large tuberculosis sanatorium in one of the largest cities of the South asserted that he had seen 18,000 cases of tuberculosis and had not in a single instance found evidence of coexisting active or toxic goiter. He asserted positively that tuberculous patients are immune to goiter. I ventured the assertion that in Illinois, where the goiter problem had received considerable attention, no tuberculosis specialist could be found that would make such an assertion, because our tuberculosis specialists look for and find other abnormal conditions when they are present besides tuberculosis.

Reaction of One Disease on the Other.—Some authorities believe that "hyperthyroidism" exercises a beneficent influence on tuberculosis. This hypothesis hardly seems logical. In a disease in which metabolism is already upset, it is difficult to see how goiter, with its marked influence on the metabolic rate, can possibly have a beneficent influence. In tuberculosis, a disease characterized by prolonged toxemia, it hardly seems logical to suppose that goiter, another disease characterized by prolonged toxemia, should have a beneficent influence. The symptoms of each disease seem, as it were, to pull in the same general direction. It is difficult to understand how the sum of the symptoms of both diseases can pull in an opposite direction. If a man is struggling under a load, one does not make his way easier by placing another load on his back.

The erroneous conception concerning the favorable influence of goiter on tuberculosis could not have arisen if the pathologic sequence of the changes in the thyroid gland had been kept in mind. Quite early in tuberculosis there is evidence of toxemia. The toxemia of tuberculosis exercises a noxious influence on the thyroid tissue; after some time there is evidence of thyroid dysfunction. The summation of the symptoms of both diseases causes, I am inclined to think, the extremely toxic symptom complex that sometimes is seen in certain early cases of pulmonary tuberculosis in which the condition in the chest is insufficient to account for the severe illness of the patient. Finally, as a result of prolonged and continuous toxemia, degeneration or sclerosis of the thyroid tissue with obvious enlargement of the gland takes place, and with this degeneration a consequent reduction or disappearance of the thyroid symptoms occurs.

With the disappearance or decrease of symptoms of thyrotoxicosis, the general condition of the patient seems to undergo a relative improvement. This relative improvement, which often occurs at about the time that increase in the size of the gland is observed, is probably the basis for the belief that goiter exercises a favorable influence on tuberculosis.

It should not be forgotten, however, that a noxious thyroid secretion, allowed to operate for long periods during the early stages of the disease, has probably done irreparable harm that could have been profitably and efficiently prevented by early proper thyroid treatment.

Sanatorium Treatment.—Probably some cases of exophthalmic goiter subside or are greatly improved as the result of a rest period of three or six months in a sanatorium. The cases of coexisting exophthalmic goiter and tuberculosis are also greatly benefited. As the tuberculosis becomes arrested, the toxemic irritant to the thyroid is removed. The patient experiences simultaneous improvement in the two diseases.

Medical Treatment.—The medical treatment will follow along the general lines of treatment for tuberculosis, summarized as rest and hygiene.

As regards the use of iodine, even as a preoperative measure, more care is necessary than in the ordinary case of exophthalmic goiter. In the active case of tuberculosis, the exhibition of iodine is said by authorities on tuberculosis to be liable to upset the digestive apparatus and even to provoke a hemorrhage, and this fact must be borne in mind.

Surgical Treatment.—Indications: Considerable prejudice exists in some quarters against operative procedures of consequence in the presence of pulmonary tuberculosis. One of the greatest of pioneer surgeons said in his Golden Rules of Surgery, "Pulmonary tuberculosis is always a contraindication for any serious operation." Undoubtedly this is justifiable to some extent. A prolonged operation, particularly under general anesthesia, exercises a deleterious influence on the condition of the actively tuberculous patient. An ether anesthetic should not under any circumstances be given in the "open case" of tuberculosis, except in the face of an emergency. However, thyroidectomy today has become so simplified that in an emergency it may be applied without detriment even in the actively tuberculous case for relief from severe thyrotoxicosis. Local or gas anesthesia may be used in practically all cases. The preparation and psychic control of the patient may demand a little more time and patience, but the end-results achieved justify the effort.

As regards the direct indication for operative treatment, it is largely a question of individual judgment and experience. The early stage of tuberculous involvement, when the thyroid dysfunction is also in all probability quite recent, is of course the ideal time for operation. But the difficulty of making a positive diagnosis of goiter that demands operation is so great at this stage that such operations are rare indeed. It would take a brave surgeon to undertake operation in such cases before the result of sanatorium treatment has been determined. So the diagnosis and the treatment of the early cases will necessarily remain in the field of the tuberculosis specialist.

Cases That Are Surgical.—First, the chronic tuberculous patient whose condition has been repeatedly classified as arrested and who now has a toxic goiter. The goiter may be either the exophthalmic or the toxic adenoma type. A pulse rate higher than is consistent with the temperature curve is the one symptom that is present in almost every case. Other symptoms are, of course, present according to the kind of goiter and its stage of development. Surgical treatment is very satisfactory in this class of cases.

Second, the tuberculous patient who has improved under sanatorium care and shows arrest of the symptoms of tuberculosis but who still has an active goiter. Symptoms of mild exophthalmic goiter with the cardiac symptoms predominating are usually present. Thyroidectomy completes the cure.

Third, the patient with advanced pulmonary tuberculosis who has a goiter of long standing when a rapid increase in the severity of the symptoms due to the coexistence of tuberculosis toxemia and thyrotoxicosis develops rather suddenly. Removal of the goiter is usually followed by spectacular improvement. The inevitable death of the patient from tuberculosis is probably merely postponed. But the immediate results are so satisfactory that the operation is justified. Usually, it may be said, if the patient has resistance to carry the load of both diseases she should improve remarkably when the thyroid toxemia is removed.

Contraindications.—In a general way, if the nature and extent of the tuberculous lesion is such that hope of arrest or recovery is out of the question, even if the load of thyrotoxicosis is removed, operation is contraindicated.

REPORT OF CASES

In the last fifteen years I have operated on more than 400 patients who were known to be tuberculous before operation, and practically all have gained in weight and made satisfactory improvement. A few of these may be reported briefly:

Case 1.—Margaret O., aged 19 years, operated on in May, 1915, had been under treatment for five years for tuberculosis. Several laboratory examinations were positive. She had some rise of temperature afternoons, especially during and after the menstrual periods. She ate ravenously but weighed only 94 pounds (42.6 Kg.). The pulse rate was from 150 to 170. The goiter was removed under local anesthesia. In one week the pulse rate dropped to below 100, and October 3 of the same year her weight was 134 pounds (61 Kg.). She is living today, and seems to have recovered from the tuberculosis.

Case 2.—Mrs. C. J. had a positive diagnosis of pulmonary tuberculosis made at various times during 1912, and again in 1914 and 1915. She developed marked symptoms of exophthalmic goiter in 1916. Operation with local anesthesia was done in August, 1916. The pulse rate dropped from 140 to 84. Her nervousness and insomnia disappeared. She gained 32 pounds (14.5 Kg.) in four months, and seems well at the present time, ten years after her thyroidectomy.

Case 3.—Miss B. G., aged 23, a student at the University of Illinois, had been tuberculous for years. Tubercle bacilli were found in the sputum at various times. She developed symptoms of exophthalmic goiter during the winter, and a hyperplastic goiter was removed, April 2, 1917. She returned to school in eight days. Her pulse dropped from 150 to 88. Nervousness, insomnia and the afternoon rise of temperature disappeared. She finished her college course, and now, nine years after the operation, is married and is the mother of a 4 year old child and seems to be in perfect health.

SUMMARY

The rather frequent coexistence of goiter and tuberculosis is not sufficiently appreciated.

Diagnostic difficulties are great, owing to the similarity of the clinical picture in the two diseases.

The sequence of pathologic change in the thyroid explains the relative severity of the two diseases at different periods.

Three Types of Diagnostic Problem in Early Cases.—1. The incipient case of tuberculosis, without demonstrable lung lesion, resembling exophthalmic goiter.

2. The forme fruste type of exophthalmic goiter resembling early tuberculosis.

3. Coexistence of tuberculosis and goiter; coexistence of the two diseases, which is comparatively frequent, as shown by statistics.

Three Types of Cases That Are Sometimes Surgical.—1. Chronic tuberculosis with toxic goiter.

2. Arrested tuberculosis with toxic goiter.

3. Acute cumulative toxemia resultant from coexisting pulmonary tuberculosis and toxic goiter.

Treatment.—Early cases: medical; rest and hygiene as for tuberculosis. Late cases: surgical when positive symptoms of thyrotoxicosis are unquestionably present.

THE OCCURRENCE OF STAPHYLOCOCCUS AUREUS INFECTION WITH A SCARLATINIFORM RASH [*]

FRANKLIN A. STEVENS, M.D.
NEW YORK

Considerable advance has been made in the last few years in the diagnosis of scarlet fever. While the typical case has seldom confused the experienced clinician, the diagnosis of many borderline cases has been difficult. These atypical exanthems have fallen into two groups. The first group comprises cases resembling scarlatina in many respects yet with sufficient deviation from the usual signs and symptoms to render the diagnosis questionable. Filatow [1] and Dukes [2] have described epidemics of such peculiar exanthems. Sporadic instances of infection also occur. The second group includes the exanthems associated with surgical infections. Malfatti [3] described puerperal scarlatina in 1801, and Paget [4] noted in 1864 that scarlet fever might accompany the infection of wounds. Since the etiology of scarlet fever has been established, we know that puerperal and surgical scarlatina occur; but clinical diagnosis is difficult unless the infection follows intimate contact with known cases of scarlatina. After studying the situation carefully, Litten [5] believed that in most instances accurate diagnosis was impossible.

Since Dochez [6] described the preparation of an antitoxic serum with cultures of the streptococcus isolated from scarlet fever, and the Dicks [7] published their account of the toxin occurring in filtrates of similar hemolytic streptococci, accurate methods of diagnosis have been available. Some of these methods are more practical than others. The least time consuming is a modification of the Schultz-Charlton test with convalescent scarlatinal serum. When either convalescent serum or scarlatinal antitoxin is injected intracutaneously in an area covered with a florid rash, blanching occurs in approximately twenty-four hours. This test is apparently quite specific. It occurs only in scarlatinal rashes. Those which are known to be due to other causes do not blanch. The second procedure is time consuming and requires technical skill. Cultures of the throat or wound are examined for the presence of hemolytic streptococcus. If this streptococcus is not found in three or four cultures made when the rash first appears, scarlet fever is excluded. If the streptococcus is found, a presumptive diagnosis is possible if the clinical picture closely resembles scarlatina. In questionable cases several colonies are transferred to broth, and after four days filtrates of these cultures are studied for the presence of scarlatinal toxin. Other methods are available, but they are either too technical or have not been sufficiently substantiated to be employed as routine procedures.

We have observed a number of exanthems in which there was considerable doubt as to the diagnosis. The methods just enumerated were applied in these instances to reach an accurate conclusion as to the etiology. A great majority were proved to be scarlatina. Instances have occurred in which one or the other of the methods failed—the rash did not blanch or the scarlatinal streptococcus was not recovered. In the majority, however, the results of one or both of the procedures were positive. In rare cases neither the culture nor the skin test gave evidence of scarlatinal infection. In three such cases we have isolated *Staphylococcus aureus*. In these instances the bacteriologic and immunologic data show that the entire picture was the result of infection with staphylococcus.

CLINICAL AND BACTERIOLOGIC DATA

The three cases of *Staphylococcus aureus* infection were first studied to eliminate the possibility of infection with the hemolytic streptococcus. Secondly, the staphylococcus isolated in each case was studied to show that it was responsible for the rash. With a few modifications, the methods employed in the study of the streptococcus were applied to the investigation of the staphylococcus. Blanching tests were done in the same manner with staphylococcus antitoxic serum as they have been done in the past with scarlatinal antitoxin. The details of the methods employed in demonstrating scarlatinal toxin in streptococcus filtrates need not be given. They have frequently been fully described in the recent literature. To obtain the toxin with *Staphylococcus aureus*, the strains were grown in 4 per cent peptone broth for four days in an atmosphere of carbon dioxide. Filtrates from these cultures were injected into the skin of rabbits, and the sites of the inoculations were carefully observed for inflammation and necrosis. Neutralization experiments were then done to prove the specificity of this cutaneous reaction. Filtrate and staphylococcus antitoxic serum were mixed, incubated and injected intracutaneously. Controls were prepared with filtrate and antiscarlatinal serum. Three antiscarlatinal serums were tested before one was found that did not contain appreciable amounts of staphylococcus antitoxin. This was a highly potent scarlatinal antitoxin and was employed in these control reactions. The results of the bacteriologic studies have been included with the clinical data in the following case histories:

REPORT OF CASES

CASE 1.—A girl, aged 12 years, had several hordeola in succession. Six weeks later a sudden sharp pain in the thigh was accompanied by a chill and fever. She was nauseated. Her temperature was 102.5 F. The following day a scarlatiniform rash appeared on the chest and face. The thigh was not painful but was tender on pressure. The rash slowly extended to the extremities and abdomen. The progression of the rash was typical of scarlet fever but not as rapid. It was never well marked over the extremities. There was slight circumoral pallor, and the margins of the tongue were red. She did not admit angina, but the throat appeared slightly inflamed. After three or four days the rash faded, disappearing from the face and body first. Moderate fine desquamation was observed ten days later. The thigh continued to be tender and required surgery. A collection of pus was found, which yielded a pure culture of *Staphylococcus aureus*.

Cultures were obtained from the throat of the patient on the second and third days of illness, but hemolytic streptococcus was not found. On the second day 0.5 cc. of scarlatinal antitoxin was injected into the skin of the abdomen, but the rash did not blanch at the site of inoculation. Filtrates obtained from a culture of the staphylococcus isolated from the pus gave necrosis when injected into the skin of a rabbit. This cutaneous reaction was prevented when staphylococcus antitoxic serum was mixed with the filtrate. Scarlatinal antitoxin did not prevent the necrosis

Case 2—A child, aged 8, complained of angina one forenoon. When seen, two days later, the temperature was 104 F. The fauces were then intensely swollen and the submaxillary chains of lymphatic glands were enlarged and tender. The face and body were covered with a fine punctate erythema, which was most marked over the chest and in the axillae. The cultures of the throat at this time showed numerous colonies of *Staphylococcus aureus* but none of hemolytic streptococcus Intracutaneous injections were made with both staphylococcus and scarlatinal serums No blanching occurred at the site of the inoculation with the scarlatinal antitoxin. The staphylococcus serum gave partial blanching over an area 6 cm in diameter. The blanching was *not as intense as that* usually occurring in scarlatinous rashes after intracutaneous injection of scarlatinal antitoxin The exanthem had completely faded on the sixth day of illness. Pus containing *Staphylococcus aureus* was obtained from an incision into the left peritonsillar area on the tenth day. Moderate desquamation began twelve days after the onset.

Cultures of the staphylococcus from the pus were made in proteose peptone broth The filtrates produced necrosis in the skin of rabbits This necrosis was prevented by staphylococcus but not by streptococcus serum

Case 3—The history of this case is so similar to the one preceding that the clinical details are not given. The throat cultures showed numerous *Staphylococcus aureus* colonies and a few of hemolytic streptococcus This streptococcus did not produce toxin The rash was partially blanched by an injection of *Staphylococcus aureus* serum, but no such effect was observed with scarlatinal antitoxin. In this case a peritonsillar abscess apparently opened spontaneously. The staphylococcus obtained from the throat culture produced a toxic substance with necrotizing properties similar to those of the strains from the other cases We were unable to obtain blood from these cases for observations on the antitoxic content of the serum.

COMMENT

The essential facts concerning the mechanism of the toxemia and the rash in scarlet fever are now fairly well understood. The exanthem is apparently caused by the toxin of *Streptococcus scarlatinae* in the blood. When antitoxin appears in the circulation in sufficient quantities, the toxin is neutralized[8] The rash then fades and the growth of the organism in the throat is inhibited. The blanching phenomenon is merely the expression of a local passive antitoxic immunity. Many adults who have not had scarlet fever have sufficient circulating antitoxin to give a negative Dick test and to prevent the occurrence of a rash in event of infection with streptococci that produce scarlatinous toxin.[9] In some of these individuals there is apparently sufficient antitoxin to prevent initial infection with these bacteria; in others, pyogenic infections may occur but there is no exanthem.

The literature is replete with references to the toxic properties of filtrates of cultures of *Staphylococcus aureus*. Many of these references are as significant as certain of the older contributions on the relationship of the hemolytic streptococcus to scarlet fever. Von Lingelsheim[10] observed necrosis in the skin of rabbits after the intracutaneous injection of filtrates of the staphylococcus. Later Neisser and Wechsberg[11] repeated these experiments. They found that the toxic property of the filtrates was destroyed at 56 C. and that rabbits could be immunized both actively and passively. The immunized rabbits no longer reacted to intracutaneous inoculations with the active filtrates. Parker,[12] who prepared the antitoxic serum employed in these experiments, has found that neutralization tests may be carried out in animals with filtrates and serums similar to the neutralization of scarlatinal toxin in the human skin. Several types of reactions occur when these filtrates are injected intradermally in man. Coenen[13] has described a reaction similar to that obtained with tuberculin. In addition he describes a generalized erythema with headache, fever and vomiting, occurring in children after single injections of filtrate. These reactions in children are most noteworthy since they resemble the reactions with Gabritchevski's[14] vaccine and reactions more recently obtained with filtrates of *Streptococcus scarlatinae* employed for immunization.

A comparison of the scarlatinal streptococcus and *Staphylococcus aureus* shows numerous similar properties. The production of a toxin with a reasonable degree of cutaneous specificity is common to the two. The staphylococcus toxin is perhaps the less specific of the two. So far it has not been clearly differentiated from the leukocidin. Both bacteria may produce rashes during an infection, and these rashes may be blanched by specific antitoxic serums. Rashes, malaise and fever result from the injection of filtrates of either bacterium in children. Apparently the clinical pictures in certain types of infection with these cocci are almost identical.

One objection may be raised: Rashes are infrequent with staphylococcus infection, yet no other pyogenic bacterium is as widely distributed. This situation is not beyond explanation. *Streptococcus scarlatinae* may produce pyogenic infections without rash if the blood of the infected person contains antitoxin. We have examined the serum of eight normal persons and have found that all were capable of neutralizing the cutaneous reaction with toxic staphylococcus filtrates. The situation is probably comparable to that existing in scarlatinal infection, but the occurrence of staphylococcus antitoxin is apparently more universal than the occurrence of scarlatinal antitoxin in the blood of normal persons.

CONCLUSIONS

1. An exanthem may accompany *Staphylococcus aureus* infection. This exanthem is distinguished with difficulty from the rash occurring during infections with *Streptococcus scarlatinae*.

2. These cases may be distinguished by the absence of scarlatinal streptococcus, the presence of the staphylococcus, and positive blanching phenomena with staphylococcus antitoxic serum.

PSEUDO-EPITHELIOMATOUS HYPERPLASIA AT THE MARGINS OF CUTANEOUS ULCERS

WITH ESPECIAL REFERENCE TO HISTOLOGIC DIAGNOSIS *

CLEVELAND WHITE, M.D.†
Associate in Dermatology and Syphilology, University of Buffalo
BUFFALO
AND
FRED D. WEIDMAN, M.D.
Professor of Dermatological Research, University of Pennsylvania
PHILADELPHIA

That the histologic picture at the margins of chronic or subacute cutaneous ulcers often simulates or actually reproduces that of carcinoma cutis is common knowledge to the pathologist. This would especially apply to the more highly differentiated type of epithelioma, approximately grade 1 of Broders.[1] It is well known that there are many irritative factors which may lead to mimicry of malignant hyperplasia of the epidermis, such as cutaneous blastomycosis, bilharziasis of the rectum, Paget's eczematoid dermatitis, and around pellagrous dermatitis.[2] In all these, the histologic picture may at times be quite good for a malignant growth, but we learned long ago that a malignant condition microscopically was not necessarily a malignant condition clinically; i.e. not a matter of life and death to the patient. In some classes of cases it has thus developed that we have had to require in addition some of such clinical changes as recurrence, tissue permeation and destruction, metastases, anemia and cachexia before pronouncing them malignant.

However, it still remains that some of the hyperplasias in connection with the foregoing conditions finally amount to cancerous ones, and since the problem, *the diagnosis of cancer, is vastly more important* in its beginnings than in the advanced stages, it is incumbent on physicians in practice to anticipate the tragic late expressions just indicated and address themselves willy-nilly to the more uncertain histologic ones which they see in the earliest stages. Heretofore, as far as we can find, this problem in histologic diagnosis has been stated only as a generality. In this communication it will be analyzed more closely in detail, and an *attempt will be made to establish quantitative standards* for, or at least leads to, the establishment of a personal equation as to what level and other qualities of hyperplasia may be expected in subneoplastic epidermal hyperplasia.

This is an exacting, perhaps ambitious, program which can never, from the nature of vital processes, accomplish all its aims, and cannot pretend to supplant a ripe histologic experience. The acid test, that is, the clinical outcome, has been applied to each case in this series and is paramount to the situation.

This issue challenges interest from both pathologist and the clinician if for no other reason than that it involves treatment and prognosis vitally important to the patient; certainly, it falls especially in the province of the dermatologist to make the attempt to interpret the histology of skin ulcers as closely and severely as possible. To facilitate this, and to acquaint ourselves with appearances that may occur in this connection, it is proposed here to record not only the verbal descriptions but also pictorial representations of several steps of epidermal hyperplasia from obviously simple ones to equally obviously neoplastic ones.

The need for immediate attention to this situation was forced on us by sections from an ulcer on the leg of a boy, aged 15. He presented three traumatic ulcerations about 2 cm. in diameter on the left shin; they had refused to heal for three months, and factitial elements could not be detected which might have prevented normal epithelization. The histologic picture was regarded by us as that of prickle-cell cancer (fig. 4). Following wide surgical excision of the ulcers, the further histologic examination failed to confirm the biopsy diagnosis; clear-cut cancer could not be found in numerous sections from three large portions of material. From other cases which have come under observation and in which the ulcerations have healed or are healing under local symptomatic treatment, two have been selected in addition to illustrate the situation; *since the histologic picture in all was more or less* suggestive of malignant epithelial hyperplasia, they are used herewith as the basis for this paper. It must be understood that the considerations in this paper throughout apply only to the earliest stages of malignant conditions in borderline cases, not to those which have proceeded to disorganization of the corium and infiltration of subcutaneous parts.

HISTOLOGIC DIAGNOSIS

There are several well established criteria and principles which determine or at least help to differentiate histologically between neoplastic and non-neoplastic epidermal hyperplasia. Most important is the embryonic or vegetative character of the cell as seen in the hyperplastic parts—best in the deeper regions. Of course, this presupposes knowledge of the normal or adult type of cell, which may generally be acquired by comparisons with cells in more normal parts of the section. The embryonic character is manifested in several days. It is stated in the textbooks that the nucleus is large, hyperchromatic, and well chromatinized. (Hematoxylin and eosin stained sections are regarded as standard in this paper.) The cytoplasm has a rounded-off contour; its substance is more hyaloid than normal, and is perhaps more basic in tint or at least different in tint from the more normal cells elsewhere. There is an absence of vacuoles and edema and other evidences of normal metabolism such as may be exhibited in the more normal parts of the section. Levine[3] states that the type of cell that appears in human cancer is distinguished from other cells on the basis of size and normal cycle of karyokinetic division, the type of division being of the most aberrant character in cancer; this is true in advanced cases, but it is not certain that these extreme types are seen in the early stage with which this paper deals.

Another characteristic of the malignant acanthosis is, of course, deep permeation of the corium. But how deep? This cannot be answered categorically, but there are limitations to non-neoplasatic permeations. Thus, in some inflammatory dermatoses, such as eczema, in which the interpapillary pegs may be highly hyperplastic, they may readily attain the level of the sweat glands, but we have never seen them reach more deeply than this. The presence of epidermal infiltrations between this level should strongly incline one toward the diagnosis of cancer.

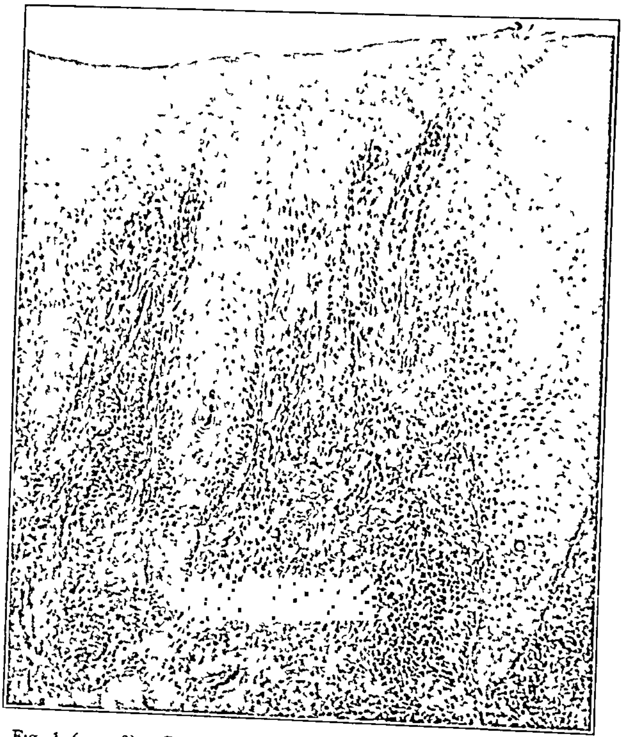

Fig 1 (case 2) —Grade 1 hyperplasia, such as may be seen in many chronic cases of dermatitis This section came from the margin of the ulcer, the other margin of the same ulcer is seen in figure 4 The extreme irregularity in form of pegs, such as is seen in grades 2 and 3, is lacking.

Other associated adjuvant (but only adjuvant) histologic features of diagnostic importance are the intactness of the basement membrane and the formation of pearls. The basement membrane is a more or less definite line, histologically speaking, separating the basal layer of the epidermis from the underlying connective tissue stroma. Actually, it is more an intangible biologic barrier plane than an anatomic structure. Among the causes of vagueness of this plane are infiltration of various cells, edema, and the occurrence of regeneration, all of which may occur in eczema and other dermatoses, and particularly as seen immediately at the margins of benign ulcers. Mitotic figures per se are of little diagnostic value, for they are seen very frequently in simple inflammations and regenerations. They are useful only as adjuncts to other features previously mentioned. Pearls, likewise, are of value only when seen in conjunction with the first three features; thus, verrucae and verrucous nevi often contain pearls. In short, there is no magical open sesame to the diagnosis of epidermal cancer. The histologic diagnosis of cancer has to be arrived at through combination of the foregoing features. Deep permeation need not necessarily be an accompaniment, particularly in very early cancer. However, when there is basement membrane penetration in the genuine cancer sense the cells at that position are always embryonic. Ewing[4] puts it that no single microscopic feature and no combinations of occasional criteria can be claimed as invariably pathognomonic of the cancer process.

To recapitulate, the most valuable single factor in the histologic diagnosis of early skin cancer is also the most subtle one and the one requiring adequate histologic experience; i. e., the assuming of younger, more vegetative qualities on the part of the hyperplastic cells involved. Deep penetration, but only if sufficiently deep (such as infiltration between sweat coils), is a most valuable criterion. After this, mitoses, pearls and irregular interpapillary pegs take second rank.

GRADES OF PSEUDO-EPITHELIOMATOUS HYPERPLASIA

These grades of pseudo-epitheliomatous hyperplasia are artificial groups set up for convenience in discussion and in appraising the biologic activity of the parts. They will be best understood if the illustrations are referred to.

Grade 1. As a matter of fact, this grade scarcely merits the designation "pseudo-epitheliomatous" because there is no difficulty in excluding it from epithelioma; it is included in these considerations, however, in order to round out the series and supply a starting point for the hyperplastic changes. The picture is that of the well known acanthosis, such as is seen in eczema of high grade (fig. 1). The pegs may reach almost to the sweat glands; the observer must be careful not to misinterpret the significance of certain islands of cells in the corium which are really tangential or transverse sections of projections from the pegs. The experienced eye will find that the embryonal qualities of cells which are seen in valid epithelioma are missing in this grade, and that there is not the slightest

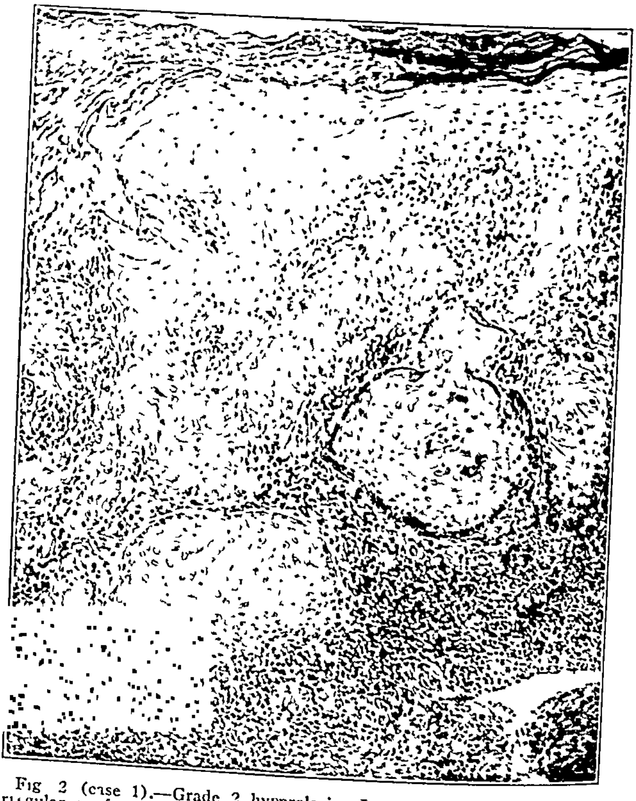

Fig 2 (case 1).—Grade 2 hyperplasia: Interpapillary pegs extremely irregular in form, but there is no subdivision into infiltrative strands.

---

[4] Ewing, James: Neoplastic Diseases, ed. 2, Philadelphia, W. B. Saunders Company, 1922, p. 465.

suspicion that the basement membrane is broken. Mitotic figures may be abundant.

Grade 2. Features here are the same as in the foregoing group, but with additions. Thus, the basement membrane is so indefinite in places that it may even be regarded as broken. At such positions the cells may be of an embryonal character nearly or quite that of genuine epithelioma. There may be pearls. The interpapillary pegs may be excessively irregular in form. The features lacking for the unqualified diagnosis of epithelioma are, first, any extensive streaming of cells through a broken basement membrane, and, secondly, any notably deep extension.

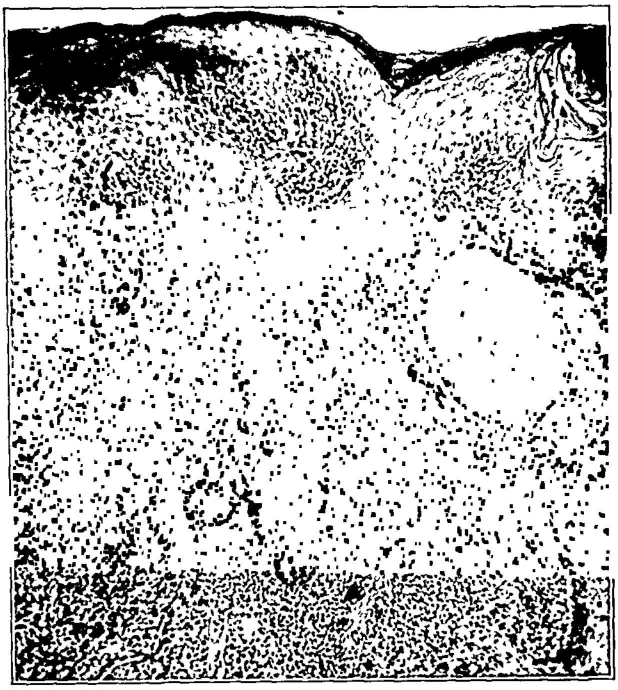

Fig. 3 (case 3).—Grade 2 hyperplasia; similar to figure 2, but showing epithelial pearls in addition.

Grade 3. Appearances here are quite those of epithelioma; by this it is meant that the only circumstances keeping such cases from the unqualified epitheliomatous cases are the clinical ones, such as absence of metastasis, or cachexia (fig. 4). Some cases of blastomycosis reproduce this picture of epithelioma, which explains the goodly number of blastomycosis cases mistakenly diagnosed as epithelioma.

REPORT OF CASES

Eight chronic cutaneous ulcerations supplied such radical pseudo-epitheliomatous appearance as to require more than passing examinations of the sections. No less than thirty sections were examined from each case; in some cases they were taken at so many different levels in the tissue block as to use it up entirely. It would be tiresome to repeat the histologic description in each case; hence only the grade of pseudo-epitheliomatous hyperplasia will be indicated as designated in the preceding section and in the illustrations; exception will be made, however, in those cases illustrated photomicrographically. It is emphasized that only those cases were included in this series in which complete healing was known to have finally taken place.

Case 1.—J. D., a boy, aged 15, complained of ulcers over the shin, present for three months, following lacerations caused by falling against a table. Various home remedies had been applied, but the lacerations refused to heal; indeed, they were slowly enlarging.

When first examined by us there were three closely placed but definite ulcerations, each about 2 cm. in diameter, on one of the shins. The borders were subacutely inflamed, slightly indurated, hyperpigmented, and not undermined. In several places there was a pearly glint, like that of regenerating epithelium. There were numerous punctate pigmented scars in the immediate vicinity of the ulcers. Specific causation could not be established, and they were finally diagnosed as simple chronic traumatic ulcers. In view of the persistence and the suspicious pearly appearance, a biopsy was performed. Much to our surprise, its histology was that of prickle-cell carcinoma (confirmed by two pathologists, both of national reputation). According to the foregoing classification, it was a pseudo-epitheliomatous hyperplasia, grade 2 (fig. 2). The patient was presented before the Philadelphia Dermatological Society,[5] Feb. 8, 1926, in view of the early age at which the lesions occurred. Eventually, all three ulcers were excised widely, although they had healed somewhat under a soothing ointment. Numerous sections from all three portions of the surgical specimens did not show evidence of cancer,—at most there were only a few minute buds extending downward at the original biopsy site. Following skin grafting by the Thiersch method, the ulcers repeatedly healed and broke down, but eventually healed completely.

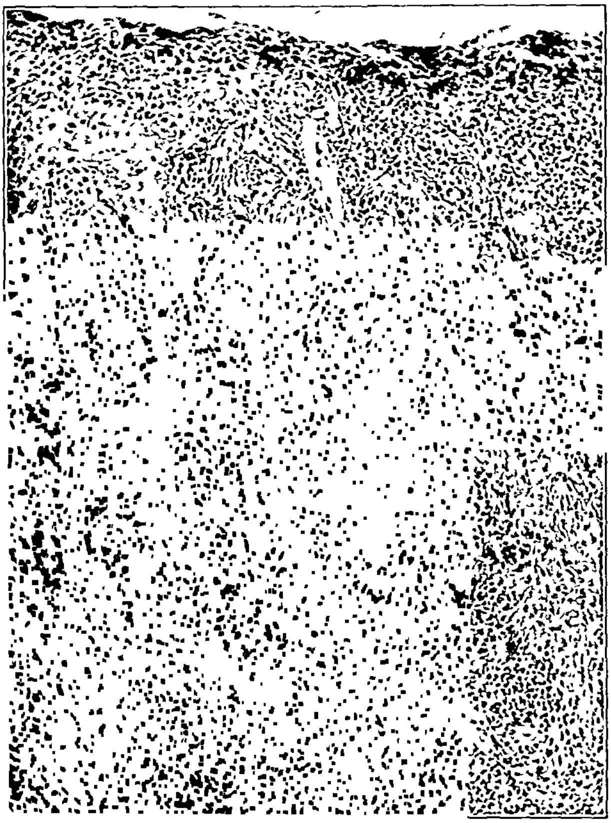

Fig. 4 (case 2).—Grade 3 hyperplasia; histologically perfect squamous-cell carcinoma.

Case 2.—M. C., A school girl aged 17, born in Italy, exhibited an ulcer on the dorsum of the right forearm, near the wrist, of two years' duration. It partially healed each summer. The lesion was about 2 inches long and half an inch wide. It was superficially ulcerated, the borders were not indurated and the base was heaped with crusted vegetations, while small droplets of pus exuded from the central portion. Adenopathy and constitutional symptoms were not present.

---

[5] White, Cleveland: Prickle Cell Carcinoma in a Boy Aged Fifteen, abstr. Arch. Dermat. & Syph. 14:93 (July) 1926.

The patient was exhaustively studied in the hospital; cultures were made and guinea-pig inoculations were performed with the result that syphilis, tuberculosis and fungus infections were reasonably excluded as causative. Sections from biopsy showed the epithelial hyperplasia (fig. 4) of squamous-cell epithelioma (grade 3 of the classification). Tissue from a second biopsy, March 17, 1926, did not show epitheliomatous changes; the prickle cells were swollen and the corium was heavily infiltrated with round cells of all kinds, but there was no resemblance to any specific granulomatous process. When the patient was seen, May 7, 1926, the ulcer had healed, but the infiltration had not disappeared. A third biopsy was performed, but sections showed only an acanthosis and a heavy round-cell infiltration of the corium. Eventually, healing was complete.

Case 3.—H. T., a colored man, aged 44, was first seen, Feb. 8, 1926, with an enlarged, swollen, ulcerated, painful tongue. The condition was of three months' duration and was progressive. He had syphilis—both as shown serologically and in sections from the tongue—but the arsenicals had little effect therapeutically. The first series of sections (from biopsy) showed epithelial hyperplasia of a degree to make one suspect cancer: grade 2 in the classification, (fig. 3). The anterior portion of the tongue was then removed surgically, and sections from its left half (site of the original biopsy) again showed definite cancer. The right half was examined in another laboratory, which could find only one small portion suggestive of a malignant condition. The stump of the tongue healed rapidly and there have not been any recurrences. The enlarged cervical glands receded after deep roentgen-ray therapy and radium. The patient has had a full course of antisyphilitic treatment, and within four months showed complete healing.

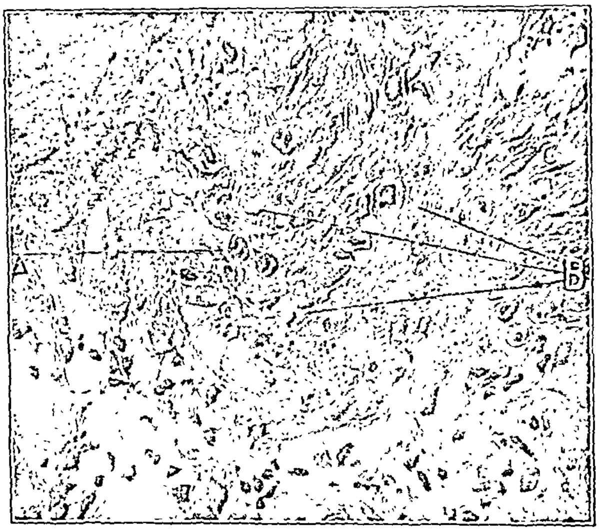

Fig. 5 (case 7).—Mitotic figures, grade 3 hyperplasia: *A*, one pair of cells which has just divided; *B*, three diasters.

This was a case, presumably, of a gummatous tongue, with ulcerations, in which early cancer had secondarily developed, at least in the histologic sense, and possibly also in the fullest biologic one.

Case 4.—J. E., a man, aged 41, had had "boils" on the neck for two years, a particularly large one having become much larger and carbuncular in the three weeks before examination. A portion of the border of the ulceration was taken at biopsy. Sections showed a degree of acanthosis compatible with a malignant process (grade 2 pseudo-epitheliomatous hyperplasia). Since the lesion did not improve under local applications, it was excised surgically. Healing was uneventful.

Case 5.—J. M., a white man, aged 32, employed as a teamster, presented an elevated, round, soft, boggy vegetative ulceration about 4 cm. in diameter on the dorsum of the left forearm. It was of one week's duration, appearing at the site of a recent wound received from a broken glass cannula in the abdomen of a dead cat. Clinically, it was a deep kerion. Smear and culture showed *Trichophyton gypseum.*

Sections from the border of the lesion showed a high grade acanthosis (grade 2) and an underlying acute suppurative dermatitis. The lesion disappeared under local treatment for deep ringworm infection.

Case 6.—M. B., colored, aged 50, with a clear cut case of syphilis, developed ulcers on the leg following trauma one year before presenting himself for treatment. They covered the lower third of the leg on its median parts. Under antisyphilitic treatment they healed in five months. Sections showed a grade 2 hyperplasia.

Case 7.—A. D., aged 33, had had one leg amputated for Buerger's disease, and presented an old ulcer on the remaining ankle. Sections showed a grade 3 hyperplasia. Within five months it had healed under ultraviolet ray therapy.

Case 8.—T. S., a girl, aged 18, entered the Buffalo City Hospital, Jan. 25, 1927, complaining of three ulcers on the right leg. They were very similar to those in case 2. The largest was about 4 cm. in diameter, and was of one and one-half years' duration. There was a flaccid paralysis of the same leg of fourteen years' duration, following an attack of anterior poliomyelitis. The only other pertinent physical observation was a slow pharyngeal reflex. Previous treatment had consisted of local applications of various types of ointments. Clinically, the ulcers were considered traumatic—in all probability factitial—but final proof could not be adduced. Mycotic examination was negative; the urine did not contain bromine or iodine, and bacteriologic study yielded only a culture of *Staphylococcus hemolyticus.* There was a 4 per cent eosinophilia in the blood. In view of the long persistence, a biopsy was taken which included the borders of two ulcers. The histologic appearance was that of grade 3 hyperplasia and compatible with beginning prickle-cell epithelioma (confirmed by a pathologist of wide experience). In view of the negative clinical and other conditions, together with our experience in previously recorded cases, only local treatment was instituted. Wet boric acid dressings were applied for two weeks to combat the slight pyogenic infection, and then fixed applications were used. March 22, 1927, all the ulcers were completely healed and the patient was discharged.

SUMMARY AND CONCLUSIONS

Whereas it has always been recognized that epidermal hyperplasia may take place at the margins of cutaneous ulcers, the extent to which it may develop histologically does not appear to have been emphasized or evaluated heretofore.

The foregoing studies show that every gradation of hyperplasia occurs among such ulcers, even to those which mimic early epithelioma perfectly, as expressed histologically.

At some of the early stages, and even when definitely developed, it may be impossible to distinguish squamous-cell cancer histologically from nonmalignant hyperplasia; there are thus definite limitations to the recognition of earliest cancer which are most unfortunate because they are so important to the patient.

We believe that the diagnosis of carcinoma under these circumstances is unjustified except when the infiltration extends to the level of the sweat glands or farther, and when the pathologist has had extended acquaintance with the behavior of hyperplastic epiderm in general. It is felt that numerous cases diagnosed in the past as beginning carcinoma at the margins of ulcers have been only exaggerated regenerative hyperplasias, and that unnecessarily radical treatment has been inflicted on patients, as in breast cases which McFarland has shown to be only senile or abnormal involution.

The premises on which cancerous changes at the margins of such ulcers have been postulated in the past deserve reexamination in this new light; i. e., whether on a histologic basis alone or supported by supplementary clinical features.

PULMONARY TUBERCULOSIS

SOME INTERESTING CASES

S. W. SCHAEFER, M.D.
COLORADO SPRINGS, COLO.

With the more general use of the roentgen ray during the treatment of cases of pulmonary tuberculosis, especially when serial pictures are taken at intervals of three, six or twelve months, our knowledge and understanding of the process of healing, as well as of destruction in tuberculous disease of the lungs, has been greatly increased. This study has shown us many interesting things, probably among the most important being the fact that tuberculous lesions heal not only by fibrosis with a subsequent permanent scar, but also and very frequently by absorption of the tuberculous deposit without any or only very slight scar tissue formation. It is of interest to know that this fact of the absorption of tuberculous lesions without the formation of scar tissue has been beautifully demonstrated experimentally by Leroy S. Gardner of Saranac Lake. The healing, the formation and the behavior of cavities are also of great interest as the various changes are observed and the results of the physical examination confirmed. Both the absorption of exudate and the gradual diminution in size of cavities are beautifully shown in the roentgenograms in case 1.

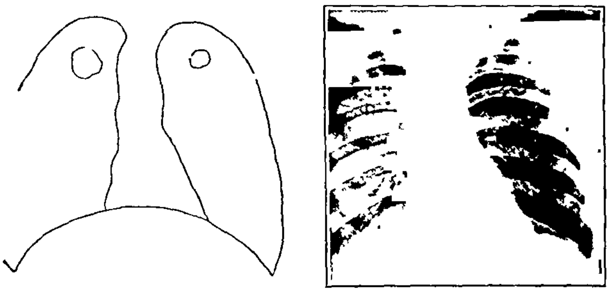

Fig. 1 (case 1).—Marked exudative type of lesion like snow over both lungs; a cavity in each apex.

REPORT OF CASES

Case 1.—F. S., a machinist, aged 30, from Detroit, first came to the free clinic, Feb. 6, 1924, after having been in the city for three weeks. He gave a history of having been ill for two years, so that he had been unable to work; he had steadily grown worse, although under medical care, and had just about used up all his savings, having $35 left on coming to the clinic. A physical examination showed a far advanced case, with marked involvement of both lungs and cavity formation at both apexes. The roentgenograms (fig. 1) confirmed the physical examination, showing an exudative type of lesion quite evenly distributed over both lungs, with a large cavity at the right apex and a smaller one at the left, but both with rather poorly defined walls. This plate suggests a snow storm falling over both lungs; the lesion is a very acute type and shows little tendency toward healing or scar tissue formation. As I understand him, this is the type of lesion that Dr. Kennon Dunham says does not heal in the East but does, sometimes, in Colorado. This patient was so ill, and the prognosis seemed so bad, especially with his very limited financial resources, that we advised him to return to his home town and enter the municipal sanatorium there. This he absolutely refused to do, saying that he had become worse there while now, although here only three weeks, he was already getting better. We communicated with the charities in his city, who acknowledged their responsibility and stated that they would take care of him if he returned there, as they had their own municipal sanatorium, but could not help him in Colorado. He again refused to return, so the local Associated Charities agreed to look after him for a short while. He was put at absolute rest in a cheap, but adequate, boarding house, and was an excellent patient. After two months he had lost his fever, and had gained 10 pounds (4.5 Kg.). This improvement continued steadily; he has gained 30 pounds (13.6 Kg.) and is able to do light work and support himself while he gets strong enough for hard work. A film (fig. 2), taken one year after the first one, Feb. 17, 1925, shows a remarkable clearing of the exudative process in both lungs, although the cavities with their more distinct wall from more adequate scar tissue formation stand out more prominently. Another film (fig. 3) taken, Oct. 9, 1925, shows that the absorption of the infiltration has continued, leaving not scar tissue but good lung parenchyma over the greater part of both lungs, and that both cavities were only about half the size they were six months before. The pathologic physical signs had entirely disappeared except at the apexes, where a few râles could still be heard on the right side; the patient had no cough or expectoration. In this case our high, dry, sunshiny climate must deserve some of the credit for this "cure," for the patient had been doing the same thing under similar conditions in a low, damp climate, and had become progressively worse.

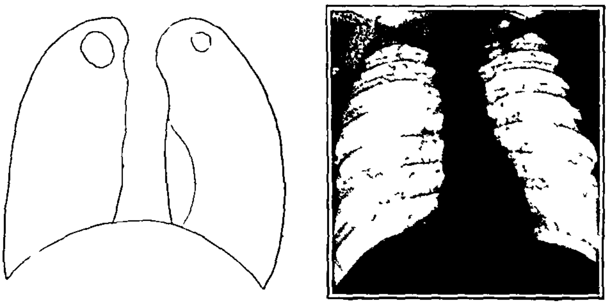

Fig. 2 (case 1).—Film taken one year later, showing remarkable disappearance of exudation, and denser scar formation around cavities.

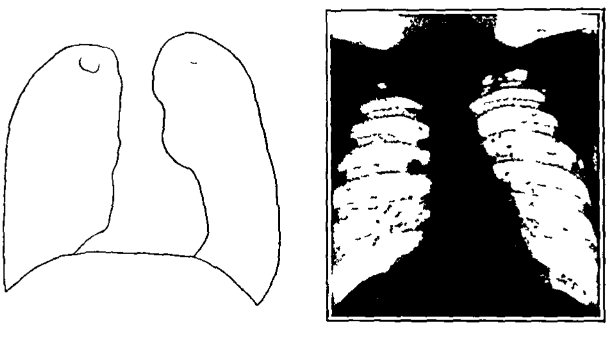

Fig. 3 (case 1).—Film taken eight months later, showing almost complete absorption of exudative process; both cavities are only about half the size they were in the previous film.

Another case is of interest as showing both the healing and the destructive processes in a far advanced condition:

Case 2.—A. S., a girl, single, aged 21, a schoolteacher from New York, seen in 1919, had a moderately advanced case of tuberculosis. On account of financial difficulties, she had to go to work in the spring of 1920 before she was well. She returned in the fall quite ill, and remained in bed during the winter and spring, 1920-1921, gradually getting worse, so that by summer she was acutely ill, with a daily afternoon rise of temperature to 103 F., an almost incessant cough, and 8 ounces of foul sputum (Gaffky 8). Physical examination revealed numerous, very moist, indeterminate râles over both lungs, with cavity formation on the right. Roentgen-ray examination (fig. 4), July 9, 1921, showed extensive parenchymatous infiltration in both lungs, more marked in the right, where there were also cavities. The induction of artificial pneumothorax on the right side had been considered, but after seeing the roentgenograms and the amount of infiltration in the left base, it seemed unwise, even though a portion of this apparent infiltration was, of course, due to the breast shadow. However, the patient was so ill and so uncomfortable that she insisted on trying the artificial pneumothorax. A week later, July 16, another roentgen-ray film (fig. 5) was made to see if it was possible to get a better picture of the left base; this was obtained and at the same time it was found that in the lapse of a week a tuberculous pneumonia was beginning in the second left interspace, just under the point where the shadow of the second rib joins the shadow of the scapula. This again made us hesitate about compressing the right lung; but the patient's condition was so critical, she was so miserable, and a fatal outcome seemed so likely unless something was done that the risk and the chances were carefully explained to her, and, not only with her consent, but at her urgent request, artificial pneumothorax was successfully induced a few days later. The compression was very slowly and carefully done, and the result was most astonishing. Almost immediately the patient lost her incessant cough and profuse expectoration, and the temperature very quickly fell below 100. In certain cases like this one, when artificial pneumothorax is successfully performed, it is one of the most remarkable miracles of modern medicine, converting a hopeless, practically moribund patient into a comfortable, cheerful convalescent in the course of a few days. This was, of course, not an ideal case for artificial pneumothorax; we were simply taking a desperate chance in the hope that if the body were freed from the absorption of poison from a massive lesion in one lung, it might be able to take care of a smaller lesion in the better lung.

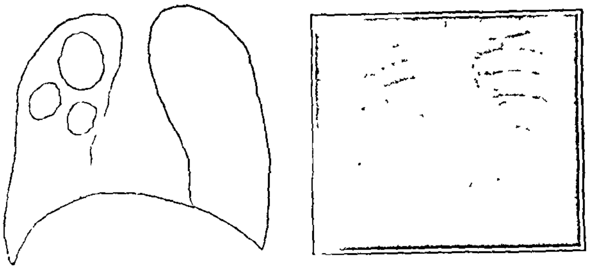

Fig 4 (case 2) —Extensive parenchymatous infiltration in both lungs, more marked in the right, where there is also cavity formation, as shown in the diagram.

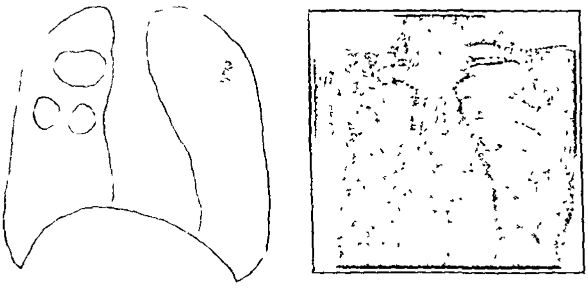

Fig. 5 (case 2) —One week later: There is a small area of tuberculous pneumonia in the second left interspace, which was not present in the preceding film.

The patient's improvement continued, and she was kept in bed for several months, although her temperature was only rarely above normal, never rising higher than 99.2 F. and that only just before her menstrual periods. Another roentgen-ray examination (fig. 6), thirteen months later (Aug. 14, 1922), showed a very good collapse of the right lung, but with one cavity still held open by stringlike adhesions going from the apex of the compressed lung to the apex of the chest wall. The left lung was apparently healing; although râles could still be heard, they were much less numerous and much less moist. Another roentgen-ray examination a year later (Aug. 13, 1923, fig. 7) showed a still better compression with the cavity almost completely closed, and the left lung apparently healed except for a small spot in the third interspace.

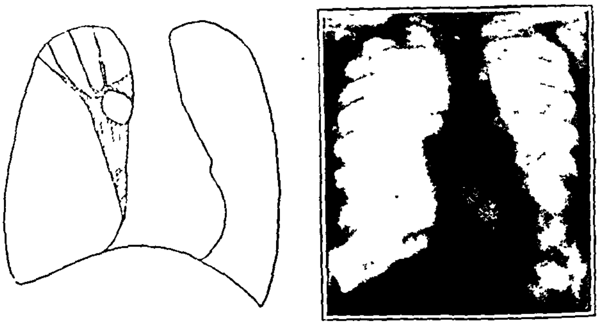

Fig. 6 (case 2).—Thirteen months later: good collapse of right lung, but one cavity held open by adhesions going to chest wall; disappearance of area of pneumonia and general improvement in left lung.

During the summer and fall of 1922, the entire year of 1923, and the spring and summer of 1924, the patient led a practically normal life, and did a considerable amount of tutoring. In the fall of 1924 she did not seem quite so well, and a few râles and roughened breathing could be heard in the left interscapular space. She was advised to stop her work and rest much more, and at the same time the intervals between the pneumothorax treatments were lengthened. Less air was introduced in an attempt to have the right lung reexpand so that the left might be compressed, but without success.

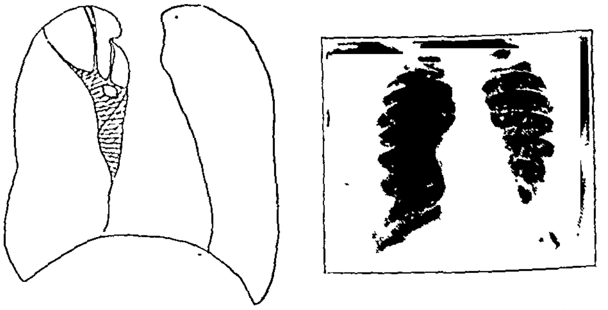

Fig. 7 (case 2).—Film taken twelve months after preceding one: better compression of right lung; great improvement in left lung except for small area of infiltration at third left interspace.

In November, 1924, fifteen months after the last roentgenogram was taken, another roentgen-ray examination was made (fig. 8), which showed a definite increase in the size and density of the area of infiltration in the third and fourth interspace, and also that the cavity in the compressed right lung had entirely closed. During the winter and spring of 1925, the patient kept comparatively quiet and felt well except for occasional attacks of what she called "bronchitis," when her cough became quite troublesome. During the summer she was fairly well, but in September she had a serious upset with high fever and much cough, from which, however, she recovered rather quickly. She remained in bed, and Dec. 3, 1925, another roentgen-ray examination was made (fig. 9), which showed a large cavity deep in the left lung where the area of marked infiltration had been in the previous plate. Two weeks later she had a tremendous hemorrhage, followed by a lobar pneumonia, and died four days later. The advisability of the induction of artificial pneumothorax in this case may be open to question, but without it she would probably have died in 1921; with it, she had four and one-half years of a very happy life.

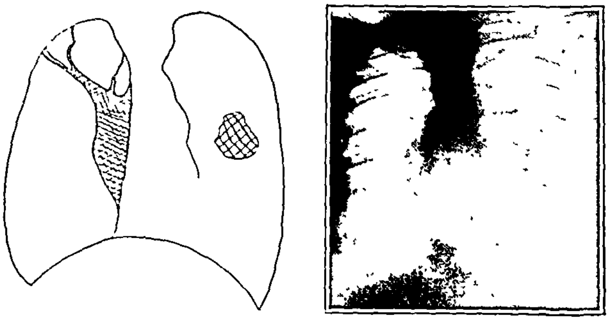

Fig. 8 (case 2).—Film taken fifteen months after the preceding one: cavity in right lung completely closed, but increase in size and density of area of infiltration in third and fourth left interspaces.

Another patient presented an interesting cavity, which again shows what remarkable results can sometimes be obtained with artificial pneumothorax even though it is not used in the orthodox manner; i. e., given only when there is one good lung:

Case 3.—A. W., a married woman, aged 25, had come out from Chicago in 1922 with a far advanced case of tuberculosis. There was involvement of both lungs, with a cavity at the right apex, and of the larynx (fig. 10). Under the routine rest and climatic treatment, with "silence" and a few local treatments, her throat trouble healed and the right lung improved slowly. During the winter of 1923-1924, following an attack of influenza, the patient became worse and in the spring was critically ill, with high fever, almost continuous cough, and much expectoration; she was losing weight rapidly, felt extremely ill, and became dyspneic on the slightest movement, such as turning over in bed. Chest examination at this time showed that the right lung was still in fairly good condition, but that over the entire left lung there was marked impairment of the percussion note; the breath sounds were very soft and distant but were accompanied both on inspiration and on expiration by numerous subcrepitant râles suggesting a tuberculous pneumonia. A roentgen-ray examination, Feb. 25, 1924, confirmed these observations, figure 11 showing marked parenchymatous infiltration over a large portion of the left lung, and a medium sized cavity with a distinct wall at the right apex. Again, this patient was so ill that it seemed as though she would live only a short while unless something drastic was done. Therefore, in spite of the cavity on the right side, it was decided to attempt to collapse the left lung. This was successfully done, with her understanding and consent, in April, 1924. Once more there was almost immediately a remarkable improvement, although in this case the lung had to be collapsed with extreme care and very slowly on account of the great dyspnea present. Another picture, taken, December 30 (fig. 12), showed a very good collapse of the left lung, as well as the almost complete disappearance of the cavity at the right apex. This is the first and only time I have ever seen apparent closure of a cavity from pressure of an artificial pneumothorax on the opposite side. During this time the patient's improvement has continued, although she still has a premenstrual rise of temperature to 99 or 99.2 and she is able to be about more and more all the time. For a while, for two or three days after each refill, she would become very dyspneic, so that we have given less air and have kept a negative pressure to avoid this. The sputum has diminished from 10 or 12 ounces in twenty-four hours in 1924 to 1 or 2 ounces; and her weight has increased from 108 pounds (49 Kg.) in May, 1924, to 146 pounds (66 Kg.) at the present time. Another film (fig. 13), taken, Feb. 6, 1926, shows that with the reduced pressure, the left lung has slightly expanded so that the cavity at the right apex can again be seen, but is much smaller than before the induction of the pneumothorax.

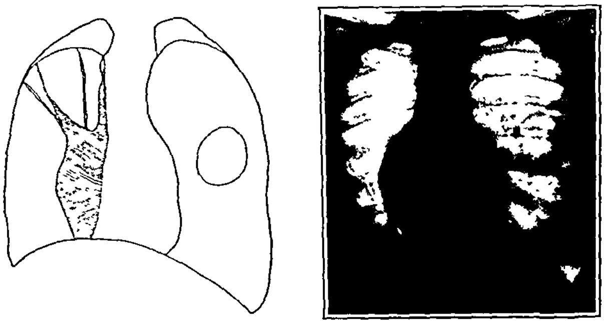

Fig. 9 (case 2).—Film taken thirteen months later: large cavity where area of infiltration was shown in previous film.

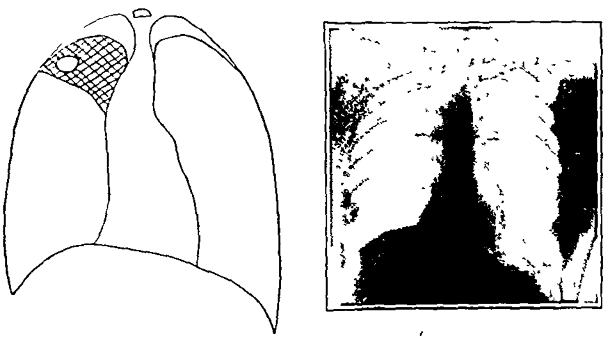

Fig. 10 (case 3).—Marked lesion with cavity formation at right apex; left lung in fair condition.

The entire right lung seems in very good condition, while the left lung shows marked absorption of the exudate, leaving good lung parenchyma with only here and there a small scar from a healed tubercle. We are again raising the pressure in the pneumothorax cavity in an attempt to reclose the cavity on the right side. The patient has not had tubercle bacilli in her sputum for the last ten months.

COMMENT

The ability to free the sputum from tubercle bacilli seems to have a definite bearing on the ultimate prognosis. In cases 1 and 3 the bacilli disappeared comparatively quickly, while in case 2, even though for months at a time the patient had less than half a teaspoonful of sputum in the twenty-four hours, this was always positive for tubercle bacilli when examined.

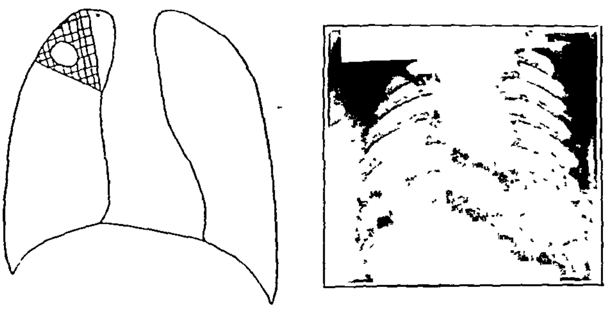

Fig. 11 (case 3).—Film taken eighteen months after preceding one; marked parenchymatous infiltration over left lung; cavity still present at right apex.

All these were far advanced cases, and the patients were kept at absolute rest for months. By absolute rest is meant rest in bed, plus the use of postural rest when indicated and the use of shot bags over the apexes when artificial pneumothorax is not given, especial attention being paid to the amount of talking a patient is allowed to do. In all three cases during the acute upsets, the patients were put on "silence," often for several weeks at a time. It is only by using rest to the nth degree that the absorption of these massive exudates can be obtained.

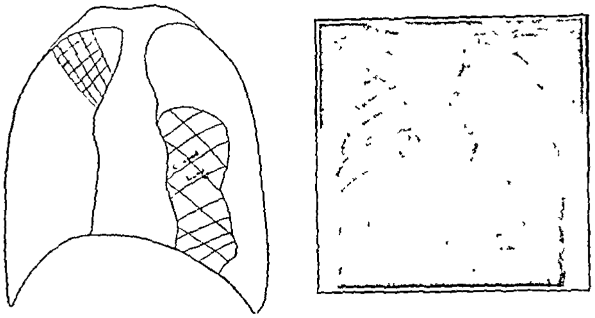

Fig. 12 (case 3).—Film taken ten months after preceding one; good collapse of left lung, with disappearance of cavity at right apex.

SUMMARY

Some of the facts brought out by this group of cases and films might be thus summarized:

1. Tuberculous lesions in the lungs do heal by absorption of infiltrations as well as by scar tissue formation.
2. Tuberculous cavities in the lung do become very much smaller with improvement, and in some cases they apparently entirely disappear as far as the physical observations and the roentgen-ray examination can show.
3. Artificial pneumothorax is often of great aid even in cases of pronounced bilateral tuberculous disease. If the body is relieved of the tremendous poisoning from a massive lesion in one lung, it may be able to cope successfully with a smaller lesion in the other.

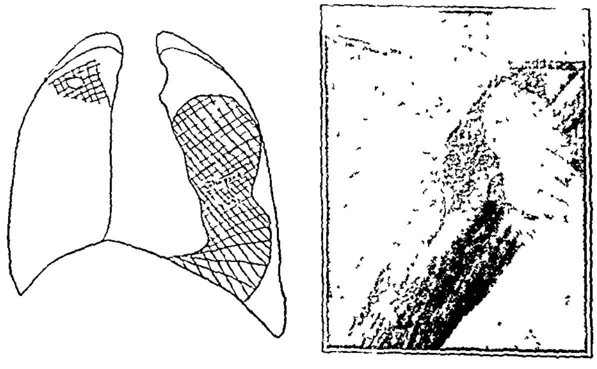

Fig. 13 (case 3).—Film taken thirteen months after preceding one: The left lung has been allowed to reexpand slightly, and the cavity at the right apex can again be seen, though very much smaller.

4. Most tuberculous patients are apparently helped by a high, dry, sunny climate such as that in Colorado, and in some cases such a climate may be the deciding factor in the recovery of the patient.

Clinical Notes, Suggestions and New Instruments

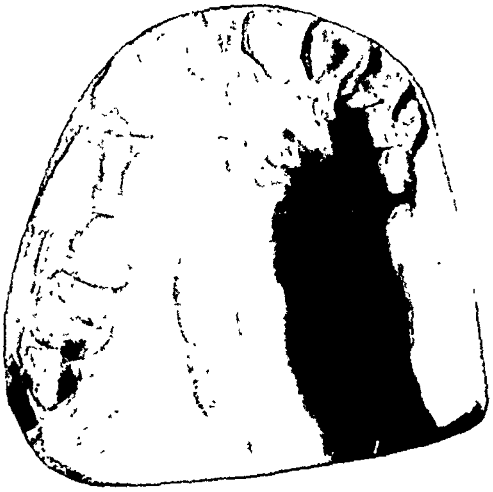
TORUS PALATINUS

JOHN E. LANE, M.D., NEW HAVEN, CONN.

In 1909, Godlee[1] began an article on torus palatinus as follows:

> In May of last year Dr. Morriston Davis brought to me a lady, aged 58, . . . *on account of a small projection obviously of bone, terminating posteriorly a median ridge in the hard palate.* . . . Up to that time I had never heard of the torus palatinus and, surgeon like, I suggested the removal of the supposed exostosis. But my ardor was damped by the deaf husband mistaking my suggestion that it was congenital, for one that it was hereditary, and stating in confirmation that her daughters had the same peculiarity. . . . Naturally, I made inquiries among the dentists, and it at once became clear that to some of them the swelling was familiar.

It is quite likely that physicians who are familiar with this not uncommon anomaly have had an experience similar to Godlee's. Several patients have been referred to me for diagnosis of the condition, and, though I recognized it for what it is, such books as I consulted for information about it did not mention it. Some time ago, when I was demonstrating a rather marked example of it, the name was supplied for me by Dr. George Blumer.



Large torus palatinus.

The torus palatinus is thus described by Merkels:

> The suture which unites the two halves of the hard palate in the midline sometimes shows so markedly raised bony borders, that, even in the living subject, a thick and broad elevation may be felt and seen. This fact was noticed many years ago. Chassaignac believed it to be a syphilitic exostosis. Kupffer and Bessel-Hagen thought it to be a peculiarity of East Prussian skulls. Neither view is correct. We must rather look upon the protuberance as an anomaly which in the first place is entirely harmless and which may appear occasionally in any locality.

After quoting this description, Korner[2] says:

> *If we add to these words of Merkel that the protuberance just described, the torus palatinus, is in many families inherited (Carabelli), we have said everything that is now known about it.*

A considerable number of examples of the condition have been observed, described in detail, and tabulated. However, this brief description is sufficient to identify the condition, which, if known to exist, is unlikely to be confused with anything else.

The patients who have been referred to me had been sent because their physicians had suspected the possibility of the protuberance being either sarcoma or syphilitic periostitis or gumma.

2. Korner, O.: Der Torus palatinus, Ztschr. f. Ohrenh. **61**: 24, 1910.

I am calling attention to the condition because it is not mentioned in most of the books on diseases of the mouth or in most other textbooks, and because, though it is frequently recognized by physicians and dentists, its name, as far as I can ascertain, is known to few of either profession.

The accompanying illustration is an example of a rather large torus palatinus. Martens,[3] Moral and Friboes[4] and Stieda[5] give detailed descriptions and additional references.

A CASE OF DIPHTHERIA PROBABLY ACQUIRED BY LABORATORY INOCULATION *

Ruth E. Taylor, M.D., Chicago

Accidental diphtheria infections in laboratories are infrequent. Mallory[1] reported an infection contracted by a student who cut his finger while removing the organs of the neck at an autopsy. Baldwin, McCallum and Doull[2] reported a case in which a physician had pricked his finger with a contaminated needle while carrying out a virulence test. Hammerschmidt[3] reported a similar infection. Riesman[4] reported an infection contracted by a bacteriologist who aspirated virulent organisms while transplanting cultures. In the cases reported, symptoms appeared within from twenty-four to forty-eight hours. The following case would appear to be one of accidental infection as the patient, a woman, aged 54, had been transferring virulent diphtheria cultures forty-eight hours before the onset of illness, and no other source of infection was known.

REPORT OF CASE

The first symptom, a mild sore throat, was noticed late in the afternoon; the following morning the patient was admitted to the hospital acutely ill and apparently very toxic. The throat was intensely swollen, and the tonsils, soft palate and uvula were covered with membrane. The posterior wall of the pharynx could not be seen. Breathing through the nose was difficult because of edema of the tissues, but a membrane could not be seen. Edema of the neck was intense, extending to the midline and well down over the clavicles. The pulse was 112; the temperature, 101.4, and the respiration, 24. The patient was given 20,000 units of antitoxin intravenously and 40,000 units intramuscularly, after three desensitizing doses of serum had been given. Six hours later edema was perceptibly increased, and she was given another 20,000 units intravenously. Twenty-four hours later the edema was decreasing slightly, and the membrane was thickened at the edges. Another dose of 20,000 units was given intramuscularly. Cultures from both nose and throat contained Klebs-Loeffler bacilli. On admission, the urine did not contain abnormal constituents. On the third and fourth days of illness, a trace of serum albumin and a few casts were present. Recovery, for five weeks, was gradual and uneventful, except for an urticarial serum reaction of three days' duration which occurred ten days after the first injection of antitoxin. On the twenty-third day after admission the patient was able to be up and about, and was taken to her home. About two weeks later, weakness of the soft palate was noticed. This was followed by partial paralysis of the pharynx and of all the skeletal muscles. A paralysis of the eye muscles was not noticed. Sensory disturbances included numbness of the hands and feet and difficult equilibration. Eight weeks after the onset of the paralysis all symptoms had disappeared, excepting numbness of the fingers and toes. Cardiac disturbance was not detected at any time during the course of the illness.

SUMMARY

The case described, which was, in all probability, one of accidental laboratory infection, is unusual in that the membrane was extensive and the toxemia severe in less than twenty-four hours after the first symptoms were noticed, and that extensive paralysis occurred, although a large dose of antitoxin had been given within twenty-four hours of the onset of illness.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

ETHYLENE FOR ANESTHESIA (See New and Nonofficial Remedies, 1927, p. 50)

Ethylene-C. L. P.—A brand of ethylene for anesthesia-N. N. R.

Manufactured by the U. S. Industrial Chemical Co., New York (Certified Laboratory Products, Glendale, Calif., distributor). No U. S. patent or trademark.

PROTEIN EXTRACTS DIAGNOSTIC-P. D. & CO. (See New and Nonofficial Remedies, 1927, p. 40).

The following products have been accepted:

*Alfalfa Pollen Protein Extract Diagnostic P. D. & Co.‡ Bean (Kidney) Protein Extract Diagnostic P. D. & Co.**

Prepared by the method given in New and Nonofficial Remedies, 1927, p. 40.

TYPHOID VACCINE (See New and Nonofficial Remedies, 1927, p. 365)

Parke, Davis & Company, Detroit

Typhoid Vaccine (Prophylactic).—(See New and Nonofficial Remedies, 1927, p. 369). Also marketed in packages of one 20 cc. vial (Bio 431) containing 1,000 million killed typhoid bacilli per cubic centimeter.

Typhoid Paratyphoid Vaccine (Prophylactic).—(See New and Nonofficial Remedies, 1927, p. 369). Also marketed in packages of one 20 cc. vial (Bio 446) containing 1,000 million killed typhoid bacilli and 750 million each of killed paratyphoid bacilli A and B per cubic centimeter.

HORLICK'S MALTOSE-DEXTRIN MILK MODIFIER.—A mixture containing approximately: maltose, 63 per cent; dextrin, 19.5 per cent; protein, 11.5 per cent; fat, 1.4 per cent; moisture, 2 per cent, and ash, 2.6 per cent.

Actions and Uses.—On the claim that maltose is more readily assimilable than other forms of sugar, Horlick's maltose-dextrin milk modifier is proposed to supplement the carbohydrate of cow's milk.

Dosage.—Horlick's maltose-dextrin milk modifier may be used in amounts to meet the requirements of a desired feeding schedule.

Manufactured by Horlick's Malted Milk Corporation, Racine, Wis. No U. S. patent or trademark.

Horlick's maltose-dextrin milk modifier is prepared by the action of diastase on wheat flour in the presence of water. The extraction is brought to dryness under a high vacuum. Approximately 2 per cent of potassium bicarbonate is added in the manufacture of the product; about 0.66 per cent while the product is in the liquid extractive state, and about 1.34 per cent after the product has been dried.

Horlick's maltose-dextrin milk modifier is an ivory colored or cream white powder, having a sweet taste. It is soluble in water or milk and is slightly hygroscopic. When in an aqueous solution (1 in 20) it is neutral or slightly alkaline to phenolphthalein and is alkaline to methyl orange.

Add a few drops of solution of iodine to an aqueous solution of Horlick's maltose-dextrin milk modifier (1 in 10): no blue color is produced (*absence of starch*).

Determine the maltose content of Horlick's maltose-dextrin milk modifier gravimetrically by the Munson & Walker method. Determine the fat content by extraction in an extraction tube, using the neutral Roese-Gottleib method; evaporate the extraction and weigh the residue. Determine the protein content by calculation from the nitrogen content as found by the Kjeldahl-Gunning-Arnold method.

THE ADJUSTMENT TO VARYING ATMOSPHERIC CONDITIONS

Man is exposed to marked variations in his atmospheric environment through seasonal changes such as occur naturally in the temperate zones or through changing elevation in a tropical climate. These undoubtedly have some effect on his health and efficiency, and temperature and humidity have come to be regarded as the most influential factors associated with the atmospheric conditions. Man's atmospheric environment may be further altered, however within doors through influences brought about by artificial conditions of living and working, whether in the home or in the industries. There are numerous occupations involving exposure to extremes of heat and cold, dampness and sudden changes. Out of several hundreds of such industrial conditions that have been listed,[1] the following will serve to illustrate the diversity of fields in which the problems of abnormal atmospheric working conditions are likely to present themselves: makers of artificial ice, caisson workers, coke-oven workers, cold-storage plant workers, furnace workers, glass makers, hothouse workers, laundry workers, dye makers, foundry workers, miners, pottery workers, sailors, telephone linemen, and welders.

Students of hygiene are essentially in agreement that the menace of "bad air" does not consist in carbon dioxide, a natural product of expiration, or in some subtle organic poison such as was once assumed to occur. Accordingly, nearly twenty-five years ago a writer[2] emphasized the fact that a "breath poison" does not exist, that the carbon dioxide content of the air is not a correct measure of the necessity for ventilation, that injury to health proceeds from excessive heat and humidity, and that the cooling and drying power of the atmosphere is of more value than the control of impurities or of gases like carbon dioxide. It should be noted, however, that with the advent and ubiquitousness of the automobile the occasional dangers of the resulting carbon monoxide and other exhaust gases need at least to be kept in mind in discussions of modern atmospheric conditions.

Interest in the methods of combating unfavorable atmospheric conditions has been stimulated by the growing recognition of the economic advantages that result from work carried out under the most satisfactory conditions of personal activity. The benefits of proper heating and cooling and suitable ventilation can sometimes be expressed in dollars and cents as well as in terms of physiologic well being. Consequently, efforts to secure appropriate atmospheric environments have been initiated in many quarters. The science of hygiene thus has acquired the imperative duty of giving careful consideration to all that is involved in securing the most satisfactory atmospheric conditions. Experts of the United States Public Health Service[3] have pointed out that the effects on the human body of abnormal air temperatures are modified by humidity, air motion, exercise, physical condition of persons exposed, food eaten, clothing worn, and idiosyncrasy. Humidity increases the discomfort and ill effects of both high and low temperature. It has been concluded that there must necessarily exist certain combinations of temperatures, humidities and air motion that will produce the same total body heat loss by radiation, convection and evaporation, and therefore the same feeling of comfort or discomfort. Any such combinations are equivalent and have been described as "effective temperatures." Comfort, as determined by both sense and physiologic reactions, is stated to depend solely on "effective temperature."

It will perhaps be more surprising to learn from the government report that the limiting physiologic reaction caused by high temperatures, as determined by comfort, is not body temperature but the pulse rate. When this is above 135, the first symptoms of discomfort arise; when above 160, the effects range from severe to distressing. The upper limit in atmospheric conditions at which work can be performed efficiently corresponds to a dry-bulb temperature of 100 F. and a relative humidity of 30 per cent, or 90 to 95 F. in still saturated air, even when the subject is stripped to the waist. The optimal temperature at rest is around 66 F.; and with hard work the optimal temperature is 59.5; 43 F. was pronounced as too cold with or without air movement, regardless of humidity. In still air, no temperature is too low to prevent outdoor work.

The problem of human adaptation to certain tropical climates has been discussed repeatedly, and recently in connection with the "White Australia" policy.[4] Now that diseases of exogenous origin can be better controlled and averted, and that the principles of proper diet are better understood, the possible deleterious effects of climate per se demand special consideration. According to Sundstroem,[4] decrease in cooling power in the more humid parts of the tropics constitutes the principal physiologic menace to the welfare of the white races in such regions. He believes that the body is capable of setting in motion a chain of adaptive mechanisms that help to adjust threatening disproportions between heat production and heat dissipation. A lowering of basal metabolism probably constitutes one such reaction. Whether this implies a lowered "vitality" may be debated. Sundstroem asserts that some relief may ensue to the organism if it succeeds on the one hand in keeping down the total sum of active protoplasm and, on the other hand, in enlarging the relative area of skin surface. He states that evidence has been produced to indicate the existence of both these mechanisms at least in animals. Man possesses, in his perspiring integument, an effective heat dissipating organ, and we assume that his power of adaptation to a tropical climate is more or less proportional to the efficiency of his sweat glands. But, Sundstroem concludes, it is conceivable that in consequence of this profuse perspiration the burden and the risk of breakdown will only be shifted from the regulation of heat to that of water. Tropical climate seems to tend to establish a new level of equilibrium between the organism and its environment. In relation to this process the mobilization of water in the body may deserve more intensive study than it has received.

ERGOSTEROL, A PRECURSOR OF THE ANTIRACHITIC VITAMIN

Not long after the discovery that exposure of various types of foods to ultraviolet rays will endow them with antirachitic potencies, the "receptive" substance capable of becoming thus activated appeared to have been found. Independently, but at about the same time, it was ascertained by three groups of biochemists[1] that the higher alcohol cholesterol, having the characteristics then known of the pure substance, was rendered antirachitic by exposure to ultraviolet rays. Meanwhile, as was recently pointed out,[2] the earlier expressed suspicion that an impurity in the usually available samples of cholesterol may be the responsible factor concerned in the activation by ultraviolet rays has gained in importance. On the one hand, the evidence is increasing that cholesterol that is highly purified by chemical means loses the property of becoming antirachitic by irradiation; and, on the other, some success has followed the attempts to isolate and identify the effective "impurity," the so-called provitamin or precursor of vitamin D.

A recent writer has remarked that the fact that the presence of an impurity in such a well crystallized substance as cholesterol has for more than a hundred years escaped recognition by chemists is explained by the minute amount (1:2,000) concerned, and emphasizes the delicacy of the biologic test. The investigation of the nature of the "provitamin" has been facilitated of late by the introduction of spectroscopic tests in place of the somewhat tedious animal experimentation. Active cholesterol gives a characteristic absorption spectrum in the ultraviolet region. The latest evidence as to the nature of the impurity present in ordinary sterols, of both animal and plant origin, responsible for their activation by ultraviolet rays leads to the view that the receptive substance is a sterol of an unsaturated and labile type, of which ergosterol is the only known representative.

Ergosterol has been found by Rosenheim and Webster[3] to possess the same characteristic absorption spectrum in the ultraviolet as nonpurified cholesterol, the intensity of the absorption, however, being enormously increased. The biologic tests with irradiated ergosterol have been astounding in their outcome. According to the British biochemists[3] a daily dose of 0.0001 mg. of irradiated ergosterol cured and prevented rickets in rats kept on a rachitogenic diet. Even this does not represent the maximal potency of the new artificial products. As Rosenheim and Webster point out, irradiated ergosterol is therefore the most potent antirachitic substance known, 5 mg. being equivalent to approximately 1 liter of a good cod liver oil. They note further that a dose 10,000 times greater than what is at present regarded as an effective dose did not produce obvious ill effects on rats under the experimental conditions used.

THE JOURNAL[2] has maintained that, with the subject in a state of such active study and continual flux, final pronouncements should be withheld. For the moment, at least, the conclusion seems justified that the naturally occurring parent substance of vitamin D is ergosterol or a sterol possessing the same absorption spectrum and physiologic activity. The admixture in cholesterol from all animal sources (brain, eggs, gallstones) of a sterol with more than one double bond seems likely, in view of the well known occurrence in phytosterols from vegetable oils, seeds and the like of other representatives of this class, containing two double bonds. Although ergosterol was originally isolated by Tanret from ergot, and named accordingly, similar or identical sterols ("mycosterols") have been obtained from a wide range of the lower plants. The action of ultraviolet rays on ergosterol leads to an obvious physical change and the production of a yellowish resin. The nature of the intramolecular change that gives rise to the vitamin formation is at present unknown. The importance of these discoveries can scarcely be overemphasized; they also reflect great credit on the indefatigable investigators in this country and abroad who have made the striking observations.

DIET CONTROL IN NEPHRITIS

Clinicians are awakening to a realization that the dietary management of certain types of nephritis has perhaps been too rigorously "standardized" in the past. For the most part the diets prescribed are considerably limited in one direction or another; and the restricted intakes are often ordered somewhat indiscriminately for all patients in the category of renal disorder. This makes for convenience of administration, though by no means always for wholesome therapy. The general dictum for the dietary regulation is to spare a diseased kidney unnecessary functional labor, and at the same time furnish the nutrients distinctly appropriate for each case. Sometimes the application of these principles calls for a choice between disadvantages rather than a discrimination between advantages.

One of the recent changes in the dietotherapy of nephritis concerns the physician's attitude toward the protein factor in nutrition. Heretofore the beliefs, on the one hand, that protein feeding can in itself produce nephritis and, on the other, that a diminution of protein catabolism will "spare" the kidneys from the effort of excreting nitrogenous waste products have been responsible for the almost universal institution of low protein intakes in all kidney disorders. Peters[1] has recently pointed out that the loss of protein in certain types of nephritis may be considerable. In the chronic cases a consideration of the problem of nutrition must take into account not merely days but months of tendency toward a negative protein balance. Hence, the maintenance of a minimum nitrogen metabolism and at the same time of nitrogen equilibrium (that is, a condition in which an individual is not forced to draw on his essential tissues for subsistence) can be effected, according to Peters, only by the administration of adequate amounts of both protein and calories. If calories are deficient, more protein will be burned; if protein sinks below a certain level, all the calories in the world will not prevent wasting.

An important cause of prolonged depletion of the protein stores may be found in a persistent albuminuria. The excreted protein is derived from the blood plasma to such an extent as to lead sometimes to actual lowered concentration of plasma proteins. This condition undoubtedly is a contributory factor in the genesis of edema. Various forms of malnutrition, not merely those presented by chronic nephritis, may be attended with low plasma protein content and edema; and these conditions may even develop without the intervention of albuminuria. The supply of adequate protein in such instances thus promises the relief of a series of interrelated untoward symptoms. Studies of parenchymatous nephritis (so-called nephrosis or the edematous type of nephritis) have revealed the fact that patients with this condition have an enormous ability to retain nitrogen over long periods when they are fed an excess of protein, and that this nitrogen storage is not attended by an elevation of the blood nonprotein nitrogen. The only deductions one can make from these facts, Peters adds, are that these patients, either because of the wasting nature of the disease or the misguided restrictions to which they have been subjected by physicians or dietitians, have been starved of protein and are therefore retaining protein to replenish their wasted tissues. It is inconceivable, he concludes, that retention of nitrogen for the restoration of normal tissue can be deleterious to the kidney. Certainly, it does not increase blood nonprotein nitrogen. Even if it did cause moderate nonprotein nitrogen increases, it might not be harmful. In a practical way, it is advisable to remember the dictum that the malnutrition resulting from protein starvation cannot be relieved by any food other than protein. The reduction of the protein intake to a minimum in such conditions should at most be only a temporary expedient adopted, perhaps, to help control certain exacerbations associated with a high nonprotein nitrogen content of the blood and uremic symptoms.

Current Comment

ABSORPTION OF VITAMIN D THROUGH THE SKIN

The antirachitic factor, now commonly designated as vitamin D, seems to be essential for the proper development and maintenance of the skeletal structures. Apparently it is not produced within the living body of man. The necessary supply is ordinarily derived either through the ingestion of antirachitic foods or through exposure of the skin to sunlight or ultraviolet rays. The last mentioned method, while unquestionably effective, is for obvious reasons somewhat uncertain with respect to precise dosage. The alimentary path of introduction, usually the most convenient way for antirachitic therapy, sometimes though rarely interposes barriers that may impair its effectiveness. Alternative procedures are therefore desirable for exceptional emergencies. Accordingly, it has been found that subcutaneous administration of cod liver oil may lead to curative results attributable to the fat-soluble vitamins. Such a method is, however, far from welcome, owing to the extreme difficulty with which any fat can be utilized directly after parenteral introduction—that is, without the intervention of the usual digestive processes. At the Lister Institute in London it has been found by Hume, Lucas and Smith[1] that vitamin D as it is

secured in irradiated sterols[2] can be absorbed from a small area of uninjured skin in sufficient amount to supply the needs of the organism. The English investigators recall the suggestion of Hess that activation of hydrous wool fat by sunlight and its subsequent absorption through the skin is a possible source of this vitamin. The possibility of antirachitic therapy by inunction is thus presented.

THE PROMOTION OF SUGAR UTILIZATION

The physiologic performance of certain organs is improved by exercise. The muscles exemplify in striking ways the advantages that may accrue from training. They grow and thrive from use, within reasonable bounds at least. Atrophy is a penalty of disuse. Whether increased functional opportunities promote comparable reactions on cells concerned more exclusively with metabolic transformation is not similarly established. Lennox[3] has made a suggestive series of observations indicating that when duplicate amounts of dextrose are administered, either intravenously or orally, at successive intervals the response differs. The temporary hyperglycemia usually resulting is noticeably less after the first dose, thus implying a more prompt utilization. Lennox concludes that his experiments emphasize the importance of glucose as a stimulator of the blood sugar regulating mechanism of the body. Whether this augmented disposal means more rapid storage of sugar as glycogen, more rapid absorption into the tissues, or an increased rate of oxidation cannot yet be foretold. From a practical standpoint, however, Lennox suggests that possibly patients could utilize carbohydrate food better if it were given in small amounts frequently repeated.

AMERICAN TYPE CULTURE COLLECTION

In 1911 a bacteriologic collection and a bureau for the distribution of bacterial cultures was established in the American Museum of Natural History in New York. Dr. C.-E. A. Winslow was placed in charge of this collection, and a catalogue published in December, 1912, listed 350 species. By 1922 the collection had grown so that its care in New York was no longer practical. It was then established in the Army Medical Museum at Washington, D. C., under the auspices of the Society of American Bacteriologists. In 1925 the National Research Council secured a grant from the General Education Board to develop this collection and, if possible, put it on a self-supporting basis. It is now known as the American Type Culture Collection and is assembled in two parts—the fungi under Dr. Charles Thom and Margaret B. Church of the Department of Agriculture, and the other cultures under the care of Drs. George H. Weaver and Leila Jackson in the John McCormick Institute for Infectious Diseases in Chicago. The catalogue today lists about 1,440 cultures, including 256 fungi and 200 yeasts. During the year just ended, 2,750 cultures have been furnished to institutions for purposes of teaching and research, to health laboratories and to individuals. A nominal charge of one dollar per culture, with addition for packing and postage, has been made to meet expenses. Day after day the cultures are transferred and maintained in a state of purity. Here is a complete collection of micro-organisms of various species isolated by bacteriologists all over America, indeed, all over the world, and available for research and study—a collection unprecedented and of value which can hardly be estimated. Its maintenance is a conspicuous achievement for the good of bacteriologic and medical science.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

COLORADO

Personal.—Dr. Allen K. Krause, associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore, will give a series of lectures on tuberculosis, July 5-8, in Denver under the auspices of the Denver Sanatorium Association.——Dr. Henry R. McGraw, Denver, has been appointed a member of the state board of medical examiners to succeed Dr. David A. Strickler.——Dr. Joseph R. Blalock, Pueblo, has been appointed medical officer of the One Hundred and Sixty-Eighth Field Artillery (Reserve).

GEORGIA

Home of Richmond Academy of Medicine.—The historic structure which formerly was a part of the medical department of the University of Georgia, Augusta, has again been turned back to the medical school after use for years for the technical courses of the boys' high school. The building will be remodeled as a home for the Richmond County Medical Society, which will be reorganized as an academy of medicine. Its Doric columns and dome will be an interesting feature of the one hundredth anniversary of the founding of the medical school, for which celebration next year plans are being made. In its capacity as the center of organized medicine in the community, a portion will be set aside for the use of the woman's auxiliary and fitted up for the preparation of the famous suppers that precede each gathering of the county medical society.

HAWAII

Territorial Medical Election.—At the annual meeting of the Hawaii Territorial Medical Association, Honolulu, May 2-4, Dr. Arthur G. Hodgins, Honolulu, was elected president, and Dr. Forrest J. Pinkerton, Honolulu, secretary. The next meeting will be held in April, 1928, at Hilo.

ILLINOIS

Liquor Licenses Revoked.—The district prohibition administrator with headquarters in Chicago recently revoked the liquor licenses of the following for violation of the prohibition law and regulations:

Dr. Mat Bloomfield, Joliet
Dr. Cyril L. Hale, Chicago
Dr. Robert S. Kemp, Calumet City.
Dr. George G. O'Brien, Chicago

Personal.—Dr. Robert G. Bell has resigned as assistant medical director of the Oak Forest Tuberculosis Hospital, Oak Forest, to become medical director of the Champaign

---

County Tuberculosis Sanatorium at Urbana.——Dr. Charles L. Weber assumed the duties of health officer of Cairo, June 1, to succeed Dr. Bellenden S. Hutcheson.——Dr. Frank Cohen, Quincy, was elected president of the Illinois Medical Laboratory Association, it is reported, at the recent meeting in Moline.

Typhoid and Tuberculosis Maps of Illinois.—The thirty-four counties in the extreme southern third of Illinois lost 116 inhabitants by typhoid during 1926; the other sixty-eight counties of the state lost only 114. The population of the thirty-four southern counties is about 1 million people, and of the other sixty-eight counties about 6 million. The state department of health has divided a map of the state into three parts illustrating the typhoid mortality. The northern third had a typhoid mortality of 1.3 per hundred thousand in 1926, the central portion, 3.3, and the southern portion, 11.8. The tyhoid death rate of the state as a whole, 3.2 per hundred thousand of population, was the lowest on record in a full year. There were twenty cities of 10,000 or more population and twenty-seven counties from which no deaths at all from typhoid were reported. A map prepared by the state health department for tuberculosis tells a different story. The southern thirty-four counties are again indicated in black with a death rate of 80.8 per hundred thousand for tuberculosis. The northern thirty-three counties of the state, also represented in black, have the death rate of 80.7; the central portion of the state is only traced in black lines for here the tuberculosis mortality fell to 60.4. For the state as a whole the tuberculosis death rate in 1926 was 76.3, a decrease of nearly 4 per cent over the previous year, while the general death rate for the state went up more than 2 per cent.

Chicago

Hospital News.—The Illinois Masonic Hospital, Wellington Avenue and King Place, has dedicated a new unit of eighty beds costing about $700,000.

Society News.—The Chicago Tuberculosis Institute was awarded the Christmas seal publicity prize offered to cities raising more than $100,000 in the Christmas seal sale at the National Tuberculosis Conference, recently, in Indianapolis. The last year's seal sale amounted to $225,000.——The Medical and Dental Arts Club met in the auditorium of the new building at Wabash Avenue and Lake Street, June 6, and was addressed, among others, by Dr. Herman N. Bundesen, city commissioner of health, on "Flood Control Problems of the Mississippi."——Dr. Frank Lee Stone addressed the Chicago Gynecological Society, June 17, on "Lipiodol and Roentgen Ray as a Diagnostic Aid in Gynecology," and Dr. Carl P. Bauer on 'Comparative Study of Convalescence in the Vaginal, Supravaginal and Total Abdominal Hysterectomy in One Hundred and Fifty Selected Cases."

Appointments at Northwestern — Kendall and Ranson Return.—Arthur I. Kendall, Ph.D., professor of bacteriology and public health at Washington University School of Medicine, St. Louis, has been appointed professor of bacteriology at Northwestern University Medical School. Dr. Kendall was formerly dean at Northwestern University Medical School. William T. Bovie, Ph.D., Medical School of Harvard University, Boston, has been appointed professor of biophysics at Northwestern; Dr. Hamilton R. Fishback, Chicago, has been appointed professor of pathology; Dr. Harry B. Culver, assistant professor of urology; Goodwin L. Foster, Ph.D., University of California Medical School, assistant professor of biochemistry, and Dr. Stephen W. Ranson, professor of neuro-anatomy, Washington University School of Medicine, has been appointed to a similar position at Northwestern; Dr. Ranson was formerly professor of anatomy at Northwestern. The new buildings on the McKinlock Campus, East Chicago Avenue near the lake, were formally dedicated, June 13-17, during a week of special clinics and meetings, which were noted in The Journal, May 21, p. 1647.

Home for Convalescent Children Affiliates with University.—The Country Home for Convalescent Children at Prince Crossing near West Chicago was formally taken over by the University of Chicago, June 13, at a ceremony presided over by President Max Mason, and attended by members of the board of trustees of the university and the convalescent home and by others. The home was founded in 1911 by Mrs. W. J. Chalmers after two years had been spent in raising sufficient funds. The property comprises 96 acres and buildings which were turned over to the university, as well as the endowment funds of about $1,200,000. The institution was founded for the care, cure and education of crippled children, and at present 101 are receiving its benefits. It will be an important link in the medical progress of the university, President Mason said, especially in connection with the work of the Bobs Roberts Memorial Hospital for Children, and in connection with the pediatric and orthopedic departments. The affiliation was first suggested several years ago by Dr. Frank Billings. The formal transfer took place, Monday, in the library of the home which was built by funds donated by Mrs. Chalmers' daughter, Mrs. Norman Williams. On the new board of trustees are Mr. and Mrs. Chalmers, Max Mason, Frederic C. Woodward, Charles H. Schweppe, Albert H. Sherer and Frank McNair, and there is a board of managers of thirty-two members.

INDIANA

Temporary Injunction Against Vaccination Order.—Judge Leathers issued a temporary injunction, June 4, prohibiting the board of health and school board of Indianapolis from enforcing an order requiring vaccination against smallpox for attendance at school. This action followed the judge's overruling of a demurrer presented on behalf of the city board of health and the school board to an injunction suit filed by opponents of the order requiring vaccination. Dr. Herman G. Morgan, secretary, city board of health, said, it is reported, that the number of cases of smallpox had increased to 224; that there was at that time an average of ten new cases a day and two deaths during May, and that the vaccination order was necessary.

Society News.—At a meeting of the Sixth District Medical Association, May 26, Connersville, Dr. Larue D. Carter, Indianapolis, spoke on "Head Injuries"; Dr. Martin H. Fischer, Cincinnati, "Arteriosclerosis," and Dr. John A. MacDonald, Indianapolis, "Subdiaphragmatic Abscesses."——Dr. Evarts A. Graham, St. Louis, addressed the staff of St. Mary's Hospital at the annual banquet, Evansville, May 25, on "Chest Surgery."——Dr. John H. Reed, Logansport, was elected president of the Eleventh Councilor District Medical Society, May 19; the loving cup for the best attendance of constituent societies was awarded to Carroll County. The next meeting will be at Delphi.——Dr. Charles S. Williamson, Chicago, professor of medicine, University of Illinois College of Medicine, Chicago, addressed the Tippecanoe County Medical Society, June 9, on "Newer Knowledge of Iron in the Anemias," and held a clinic at St. Elizabeth's Hospital on heart and kidney cases.——Dr. Virgil E. Simpson, Louisville, Ky., addressed the Muncie Academy of Medicine, April 22, on "Diabetes Mellitus."

IOWA

Dr. Griswold Goes to Michigan.—Dr. Don M. Griswold, one of several teachers at the State University of Iowa College of Medicine who resigned recently, has been appointed state deputy health commissioner of Michigan, it is reported. Dr. Griswold graduated from the University of Michigan, and was formerly director of laboratories in the Detroit Department of Health. From there he went to the International Health Board of the Rockefeller Foundation, then to the State University of Iowa College of Medicine as professor of hygiene and preventive medicine, and as state epidemiologist. Dr. Griswold for a time was the state health commissioner of Iowa.

KANSAS

Dr. Brinkley's Italian Recognition Annulled.—It appears that the University of Pavia, Italy, in July, 1925, issued a diploma of graduation from that university to John R. Brinkley, Milton, Kan., based on the recognition of a diploma granted him by the Eclectic Medical University of Kansas City, Mo. A letter from the rector of the University of Pavia states that the ratification of Brinkley's credentials has been annulled, and through the Italian consul Brinkley has been asked to return the document given him. An item in regard to the annulment of the recognition granted to Dr. Brinkley's credentials appears in the current number of the Italian medical journal *Policlinico*.

LOUISIANA

Society News.—Dr. Abraham L. Levin addressed the Orleans Parish Medical Society, New Orleans, May 23, on "Extensive Colonic Polyposis with Report of Three Cases"; Dr. Elliott Kiblinger, "Management of Labor," and Drs. Hilliard E. Miller and Walter F. Henderson on "Determination of Pathology in the Fallopian Tubes by the Injection of Iodized Oil."

Health Conference Concerning Flooded States.—A conference on health in the flooded area of the Mississippi Valley was held in New Orleans, June 5. In attendance were Hugh S. Cumming, Surgeon General, U. S. Public Health Service; Drs. William R. Redden, of the Red Cross; John A. Ferrell, of the Rockefeller Foundation; John McMullen, Allan J. McLaughlin, William C. Rucker, Knox E. Miller and Kenneth F. Maxcy, all of the U. S. Public Health Service, and the following state health commissioners: Drs. Oscar Dowling, Louisiana; Felix J. Underwood, Mississippi; James Stewart, Missouri; Arthur T. McCormack, Kentucky; Eugene L. Bishop, Tennessee; William F. King, Indiana; Valeria H. Parker, of the American Social Hygiene Association, and others. Resolutions were passed after an all-day session providing for a rehabilitation program in the seven states affected, according to which a health unit would be established in each county, consisting of a full-time health officer, sanitary inspector, public health nurse and office assistants, and a field training station in the northern part of Louisiana. The program would be financed by the state, the county, and the Rockefeller Foundation, and the Red Cross when necessary, with the understanding that the parish will take over the expenses gradually and as soon as possible. During the afternoon, the conference went aboard the tug *Sampson* to go down the river to Caernarvon to view the extent of the flood.

MASSACHUSETTS

State Medical Election.—At the annual meeting of the Massachusetts Medical Society, June 6-8, Boston, Dr. John M. Birnie, Springfield, was elected president; Dr. Thomas J. O'Brien, Boston, vice president; Dr. Walter L. Burrage, Brookline, secretary, reelected; Dr. Arthur K. Stone, Brookline, treasurer, and Dr. Walter B. Cannon, Cambridge, orator.

Boston Floating Hospital Burned.—While undergoing the annual overhauling at the dock, the Boston Floating Hospital was destroyed by fire, June 1, at a loss of about $150,000. There were no patients aboard, and the eight men in charge of the work escaped injury. The Boston Floating Hospital has been in service for several years carrying thousands of tenement children down the harbor in summer on fresh air cruises.

Harvard Declines Eugenic Legacy.—Harvard University has declined the bequest of the late Dr. James Ewing Mears of Philadelphia of about $60,000 for establishing a course in eugenics. Dr. Mears's will provided for a trust fund, the income of which was to be paid to his sister during her life, and then to be turned over to Harvard College. It was announced, May 7, that the university had voted to decline the bequest, the reason reported given being in part that Harvard College did not deem it right to pledge itself to teach somewhat permanently that the treatment of defective and criminal classes by surgical procedure was a sound doctrine.

MICHIGAN

Smallpox Increases.—During the first twenty-four days of May, 151 cases of smallpox were reported to the state health department. The state health officer is reported to have said that each day witnesses smallpox reported from communities which previously had escaped. An appeal was made to institute, immediately, a vaccination campaign among all persons who had not been successfully vaccinated within the last five years.

Society News.—Mr. H. M. Nimmo, editor of the Detroit *Saturday Night*, was the principal speaker at the joint meeting of the Wayne County Medical Society and the Alumni Association of the Detroit College of Medicine and Surgery, June 14.——Dr. Guy L. Kiefer, state commissioner of health, recently addressed the Alpena County Medical Society and physicians from surrounding towns, and gave a public address at Alpena on "Matters Pertaining to Individual and Community Health"; in the evening he addressed the physicians at a dinner on "Acute Infectious Diseases, Especially Scarlet Fever and Its Prevention and Treatment by the Use of Serum."——Dr. Don M. Campbell, Detroit, addressed the St. Clair County Medical Society, Port Huron, recently on "Otitis Media, Mastoid Infection and Complications Thereof."——Dr. Victor C. Vaughan has been elected an honorary member of the Washtenaw County Medical Society.——The Michigan Trudeau Society met jointly with the Genesee County Medical Society, Flint, May 11; Dr. Eugene B. Pierce, Flint, gave a clinic on "Bronchiectasis in Children"; Dr. C. E. Bradley, Ann Arbor, and Dr. George J. Curry, Flint, gave a clinic on bone and joint tuberculosis; Dr. Max Pinner, Northville, gave a demonstration of exudative and productive tuberculosis, and Dr. James B. Amberson, Jr., Detroit, spoke on "Roentgen-Ray Examination of the Chest." At the dinner, Dr. Clarence L. Hyde, East Akron, Ohio, spoke on "Light Treatment in Surgical Tuberculosis," and Dr. Maurice Lewison, Chicago, "Some Mistakes in the Diagnosis of Pulmonary Tuberculosis."——The Kent County Medical Society held a joint meeting with the Holmes Dental Club of Grand Rapids, recently, the principal speaker being Dr. E. C. Rosenow, Mayo Clinic, Rochester, Minn., whose subject was "Further Studies on Focal Infection and Elective Localization"; more than 200 members attended this meeting.

MISSISSIPPI

Personal.—Dr. May F. Jones has resigned her position at the Mississippi State Sanatorium on account of ill health, and will return to her home in West Point, Va.; Dr. Jones is said to be the first woman to take the state board medical examination in Mississippi. Since 1900, Dr. Jones has been engaged in service for the state of Mississippi at the State Woman's College, Columbus, the State Teachers' College, Hattiesburg, and the Mississippi State Sanatorium. Dr. Jesse L. Roark, Water Valley, will take over the duties formerly performed by Dr. Jones.——Drs. Edwin E. Benoist, Natchez, Eugene S. Bramlett, Oxford, and Ernest L. Posey, Jackson, were elected vice presidents of the Mississippi State Medical Association at the annual meeting at Jackson.

MISSOURI

Society News—Auxiliary Wants an Icebox.—The woman's auxiliary of the St. Louis Medical Society needs an icebox for their kitchen. Any member of the society who is replacing an old style icebox for a new type is requested to donate it to the auxiliary, whose kitchen, presumably, is in the beautiful building which the St. Louis Medical Society dedicated a few months ago. At the meeting of the society, June 7, medals and awards of merit for scientific achievement were presented to the following members: Drs. Evarts A. Graham, Warren H. Cole, Glover H. Copher and Sherwood Moore. Dr. Roland Hill addressed the meeting on "Congenital Pyloric Stenosis."

Horton's License Revoked at Last.—The state board of health revoked the license to practice medicine in Missouri of Dr. Ray B. Horton, of Purdy and Kansas City, May 27, after having found him guilty of fraudulently misrepresenting his educational qualifications. This case has been before the board for about two years, various legal maneuvers having been resorted to to evade trial. Horton was one of about sixty physicians cited in 1925 as the result of disclosures in diploma mill investigations to show cause why their licenses should not be revoked. When Horton was licensed in 1923, it appears that he presented credentials to the board indicating that he had completed a four year high school course, three years of study at the St. Louis College of Physicians and Surgeons, and one year at the Kansas City College of Medicine and Surgery. It was shown at the trial, it is reported, that during two of the four years he claimed to have attended high school, he was attending the Kansas City Veterinary College and that the superintendent of the Purdy high school at the time, Leslie K. Grimes, testified that the signature on the high school diploma was not his. Furthermore, during the time that Horton, according to his credentials, was attending the St. Louis College of Physicians and Surgeons, he was practicing as a veterinarian, as shown by advertisements in newspapers. Three witnesses testified at the hearing of the board that Horton had solicited money from them in exchange for his alleged influence with the old state board of health of which Dr. Cortez F. Enloe was secretary. One witness is reported to have said that he gave Horton $1,000 in cash, then took the state board examination and failed. Another witness testified that he gave Horton $500, and then failed to get an examination. The third testified that he gave Horton $500, mostly in checks, photostatic copies of which were submitted as evidence. An interesting feature of Horton's effort to obtain degrees was reported to these headquarters to the effect that pressure was brought to bear on the University of Budapest to grant him a diploma, although he was unable to pass the examination. The reports indicate that the university was led to believe that unless a diploma was granted to Horton, Hungarian physicians desiring to practice in the United States would be prevented from doing so, and that the threat was made by Horton that financial support to the university from the Rockefeller Foundation would be withdrawn if a diploma was not issued—a claim which, of course, had no basis in fact. If these statements are true, the University of Budapest was deceived. Horton's case is an illustration of the difficulty that may arise in getting rid of an improperly qualified practitioner once he has been licensed, and demonstrates the care that should be taken by licensing boards in scrutinizing the credentials of candidates.

NEW JERSEY

Society News.—Dr. Henry H. Ritter, New York, addressed the Hudson County Medical Society, May 3, on "Treatment of Certain Ambulatory Traumatisms."——Dr. Barton C. Hirst, Philadelphia, addressed the Mercer County Medical Society, May 11, on "Modern Methods of Diagnosis in the Treatment of Obstetric Conditions."——At the public meeting of the Academy of Medicine of Northern New Jersey, Newark, March 16, Elmer E. Brown, LL.D, chancellor, New York University, lectured on "The Scientist and Artist."

Dr. Dickinson Honored.—About 300 friends of Dr. Gordon K. Dickinson, Jersey City, attended a dinner in his honor at the Hotel Pennsylvania, New York, April 2, to celebrate his completion of fifty years in the active practice of medicine. At the conclusion of the dinner, a beautiful bronze figure, "The Life Saver," was presented to Dr. Dickinson by the Hudson County Medical Society as a token of esteem. Dr. Berthold S. Pollak was toastmaster, and among the speakers were Drs. Charles Gordon Heyd, John O. Polak and Judge Robert L. Cary. Dr. Dickinson established the first tuberculosis clinic in New Jersey; he was chairman of the committee that developed the city hospital in Jersey City, consulting surgeon to Christ's Hospital, and in 1919 was president of the Medical Society of New Jersey. He has been engaged in many other scientific and civic activities of the community.

NEW YORK

Memorial to Dr. MacDonald.—During the fifty-fourth annual meeting of the Association of the Alumni of the Albany Medical College, Albany, June 1, the Dr. Willis G. MacDonald Memorial was unveiled. Dr. MacDonald was formerly professor of abdominal and clinical surgery at Albany Medical College, and shortly after his death a fund of about $18,000 to construct a physiologic laboratory in the college was raised. The fund, however, not being sufficient to build the laboratory was turned over to the college, and a part of the new building which was dedicated, June 13, is to be known as the MacDonald Memorial.

Hospital News.—About 250 delegates attended the third annual conference of the New York State Hospital Association at Syracuse, recently, at which time Col. Louis C. Trimble, superintendent, New York Post-Graduate Medical School and Hospital, assumed the presidency of the association.——A group of Long Island City physicians has organized the Boulevard Sanatorium, and has filed plans for the erection of a three story, fire-proof, private hospital of about fifty beds for medical, surgical and obstetric patients at the southeast corner of Jamaica and Sixteenth avenues. There will be continuous service maintained in all departments with resident physicians in attendance, although patients will be treated by their own private physicians and will have the benefit of the consulting staff. The hospital will be nonsectarian.

Liquor Licenses Revoked.—The district prohibition administrator recently revoked the liquor licenses of the following for the reasons indicated:

Dr. Forrest Hayes, Jr., Flushing, did not in good faith issue twenty-two prescriptions for intoxicating liquor as a medicine, in that after careful physical examination of his patients he did not believe the use of such liquor as a medicine by such persons was necessary and would afford relief to them.

Dr. Hirsch L. Messman, Brooklyn, record Form 1402 and book of prescription blanks and stubs not available for inspection. Did not keep a record of prescriptions in Form 1402 prior to March 15, 1927. On inspection claimed book of prescriptions, blanks and stubs was lost or stolen and he had not then and has not since notified this office of the loss of said book. False records in Form 1402.

Dr. Joseph S. Amster, New Hampton, issued prescriptions without a careful physical examination, and not believing that the liquor was to be used as a medicine.

Dr. Ransom S. Robertson, Brooklyn, unlawfully issued prescriptions for liquor and made false entries thereon. Failed to issue prescriptions in order of the serial blank numbers. Failed to enter on prescription in duplicate in own handwriting all the data called for on Form 1403.

New York City

Hospital News.—The Jewish Memorial Hospital in the Bronx has created departments of cardiology, basal metabolism and plastic surgery, and the board of trustees will entertain applications for associates in these departments.——The New York Hospital will receive nearly 10 per cent of the residue of the estate of the late Payne Whitney; this legacy, it is reported, approximates $10,000,000.——The Jewish Mental Health Society has secured a tract of 55 acres at Hastings-on-the-Hudson as a site for a hospital for curable mental diseases, the initial capacity of which will be twenty-five beds.

Warning Against Bathing in Certain Bays.—The city health commissioner issued a warning, June 1, it is reported, against bathing in Sheepshead, Pelham and Jamaica bays and in the East, North and Harlem rivers on account of the pollution of those waters by sewage and industrial waste. The health department has conducted a survey of the waters recently, and the warning was based partly on the results of finding evidence of heavy pollution. The waters at Coney Island, Rockaway, Staten Island and Long Beach beaches are still considered safe for bathing purposes. Efforts are being made to make the waters about the city suitable for bathing, but success depends in large part on the cooperation of the people in strictly observing the sanitary laws.

Drs. Hess and Rous Awarded Medals.—The John Scott Bronze medal of the Franklin Institute of Philadelphia and $1,000 in funds were awarded to Dr. Alfred F. Hess, clinical professor of children's diseases, University and Bellevue Hospital Medical College, June 2, according to the New York *Medical Week*, for his studies on the "operative influence of light on rickets and on the remarkable effects produced by the ultraviolet irradiation not only of the living animal, but also on various foods, showing in the latter instance that the vitamin value in these substances could thus be increased." Dr. Francis Peyton Rous, pathologist, Rockefeller Institute for Medical Research, was designated for his invention of devices and the development of a filtration technic for separating from tumor cells a substance producing sarcoma in fowls.

Personal.—Dr. Charles Rosenheck has been appointed neurologist to the Midtown Hospital, New York.——Dr. Henry Dawson Furniss has resigned as professor of gynecology at New York Post-Graduate Medical School and Hospital, and has been appointed consulting gynecologist to that institution.——Dr. Alexis Carrel sailed, June 4, for France for his annual outing on his estate.——Dr. Simon Flexner of the Rockefeller Institute for Medical Research was awarded the lectureship of the Association of American Physicians at its annual meeting, Atlantic City, May 4.——Capt. John W. Cleave, Medical Corps, U. S. Army, now on duty at Governors Island, has been ordered to Honolulu for duty and will sail about June 30.——Dr. Edwin C. Chamberlain has resigned from the New York office of the U. S. Veterans' Bureau after about seven years' service.

Testimonial Dinner to Dr. Guthrie.—A group of about forty-five lay and professional friends gave a testimonial dinner in New York, June 14, to Dr. Clyde G. Guthrie, who recently resigned the medical directorship of the Lawrenceville School, Lawrenceville, N. J., and is about to locate in Cincinnati. Among those present were Drs. Lewellys F. Barker, John M. T. Finney, and Hugh H. Young, all of Johns Hopkins University Medical Department, Baltimore; Mr. F. Highlands Burns, president, Maryland Casualty Company, and about fifteen other Baltimoreans; Drs. Walter W. Palmer, Haven Emerson, Alphonse R. Dochez, William Darrach and Robert L. Levy, of Columbia University; Dr. Lewis Conner of Cornell; Dr. Wade H. Brown, Rockefeller Institute; Drs. Thomas Grier Miller, Alexander Randall, O. H. Perry Pepper, all of the University of Pennsylvania School of Medicine; Drs. Kenneth Blackfan and William L. Moss of the Medical School of Harvard University; Dr. Evans of Pittsburgh; Dr. Frank D. Conroy of Cincinnati; Mr. Thatcher M. Brown of Brown Brothers, New York; Judge Bodine of the U. S. Court, Trenton, N. J.; Mr. Frank Reid and Mr. H. M. Reid of New York, and Mr. Henry Young and Mr. C. H. Fetter of Trenton.

NORTH CAROLINA

Personal.—Dr. Wilbur A. McPhaul has been reelected city health officer of Charlotte, it is reported, at an increase of salary.——Dr. James M. Parrott, Kinston, has been appointed a member of the board of directors of the State Industrial

Farm Colony, which was authorized by the last legislature. ——Dr. Carey L. Harrington, Greenville, has taken up the duties of county physician of Durham County.

Babies' Hospital Destroyed.—The Babies' Hospital at Wrightsville Beach near Wilmington was completely destroyed by fire, May 28, at a loss of about $40,000; no lives were lost. Plans have been made for the immediate construction of a larger and fire-proof babies' hospital, and Dr. James B. Sidbury, head of the former hospital corporation, has offered to donate the site to a new corporation which, if accepted, would make it more of a community institution than a private hospital.

Society News.—About 125 physicians attended the Tenth District Association meeting at Marion, June 1, under the presidency of Dr. Charles Z. Candler, Sylva, who gave an address on "The Power of Organized Medicine." The president and secretary of the state medical society, Drs. John T. Burrus, High Point, and Lewis B. McBrayer, Southern Pines, and Dr. Charles O'H. Laughinghouse, Raleigh, secretary of the board of health, were present. Dr. Joshua F. Abel, Waynesville, has been appointed a councilor of the Tenth District to succeed the late Dr. Arthur T. Pritchard.——Twenty students completed the two year course in medicine at Wake Forest College, and received certificates to that effect at the commencement, June 2. The final two years of study are to be taken elsewhere.

NORTH DAKOTA

State Medical Election.—Dr. Thomas Mulligan, Grand Forks, was installed as president of the North Dakota State Medical Association at the meeting, May 31-June 2, Grand Forks; Dr. William F. Sihler, Devils Lake, was made president elect; Drs. John Crawford, New Rockford, and Andrew Carr, Sr Minot, vice presidents; Dr. John G. Lamont, San Haven, secretary, and Dr. William W. Wood, Jamestown, treasurer. The *Journal-Lancet* was continued as the official organ of the association, and the next annual meeting will be at Devils Lake. The registration at the Grand Forks meeting was 172. The speakers were Dr. Arthur Steindler, State University of Iowa College of Medicine, Iowa City, whose subject was "Arthopathies or Charcot Joints"; Dr. Frank E. Burch, University of Minnesota Medical School, Minneapolis, "Ocular Manifestations of Diabetes"; Dr. Frank L. Jennings, Oak Terrace, Minn., "Treatment of Pulmonary Tuberculosis"; Dr. Frederick C. Rhodda, University of Minnesota Medical School, "Prevention of Acute Contagious Diseases in Children." Drs. C. S. McVicar and William C. MacCarthy, both of the Mayo Clinic, Rochester, Minn., gave a symposium on "Diagnosis of Gastric and Duodenal Disease"; Dr Wallace H. Cole's subject was "Fractures" and Drs. William Boyd and Edward W. Montgomery of the University of Manitoba Faculty of Medicine, "Pathology and Treatment of the Anemias"; Dr. Harley E. French, dean, University of North Dakota School of Medicine, "Demonstration of Epiphyseal Lines," and Dr Edgar A. Pray, Valley City, "Intercostal Neuralgia." Dr. Paul D. Mossman, U. S. Army Medical Corps, gave a clinic on "Trachoma." Dr. N. Oliver Ramstad, Bismarck, presided at the banquet, June 2.

OHIO

Toledo Academy Establishes Endowment Fund.—The Toledo Academy of Medicine has established a $300,000 endowment fund for medical research, following the insurance plan. Members will take out policies, naming the endowment fund of the academy of medicine as beneficiaries. The fund will be augmented also by gifts during life and by bequests by will. It is expected that more than 300 policies will be taken out among the 400 members; eight were taken out on the first day the plan was in force. The endowment fund committee, comprising the trustees and president of the academy, will make all contracts and direct the expenditure of all funds in accordance with certain principles set forth in the plan. The purpose of the fund is to encourage investigation in the nature and cause of disease and the methods of prevention and treatment, and to disseminate medical knowledge for the protection of the public health. The power of the endowment fund committee may extend to the building, purchasing, equipping and maintaining of laboratories or other buildings; to owning land for breeding plants and animals; to appointing committees of experts to direct research; to cooperating with other associations engaged in similar work, and to maintaining museums. In general, the committee is empowered to perform all things necessary for the promotion of the objects of the fund. Only the income will be used, the principal being kept intact. The original suggestion for establishing an endowment fund was made by Dr. James A. Duncan at the annual meeting in January; it was accomplished in May. Dr. Duncan is head of the endowment committee.

PENNSYLVANIA

Society News.—The Tri-County Medical Society (Lebanon, Dauphin, Lancaster) will hold its annual meeting at the Colonial Country Club, Harrisburg, June 22; there will be a luncheon, business meeting, golf and cards, and the annual dinner in the evening.——Dr. Thomas D. Mills addressed the Harrisburg Medical Club, May 20, on "High Blood Pressure and the Patient"; the club's summer picnic will be held at Taneytown, Md., July 1.——Dr. William E. Wright addressed the Dauphin County Medical Society, Harrisburg, May 3, on "Clinical Manifestations on Encephalitis Lethargica."

Award of Fellowships.—The provost of the University of Pennsylvania announced, June 5, the award of fellowships in neuropsychiatry established by the Commonwealth Fund in the graduate school of medicine to Drs. Bernard J. Alpers, Philadelphia; Forrest N. Anderson, Lawrence, Kan.; William George Ferguson, Ann Arbor, Mich.; Alberta L. Jenkins, Philadelphia; Paul E. Kubitschek, Philadelphia; Norvelle C. Lamar, Philadelphia; Gerald H. J. Pearson, Ottawa, Ont., and Raymond W. Waggoner, Philadelphia. The following fellowships were also awarded: Frederick W. Sunderman, Robert M. Givin fellowships in research medicine; John R. Paul, Robert Robinson Porter fellowships in research medicine; Thomas G. Miller, Henrietta Heckscher memorial fellowship in medical research; William Blair Mosser, Bennett fellowship in surgery; Verne G. Burden, F. M. Kirby fellowship in surgical physiology; Selling Brill, Hunter fellowship in surgery; Lewis Kraeer Ferguson, Agnew fellowship in surgery; Richard A. Kern, Lewis Godey fellowship in medicine, and Edward J. Ryan, J. William White fellowship in urology.

Philadelphia

Fund for Professorship of Therapeutics.—The will of the late Dr. Milton B. Hartzell, recently admitted to probate, showed a bequest of $100,000, it was announced, June 6, to the University of Pennsylvania to establish the Milton Bixler Hartzell professorship of therapeutics. Dr. Hartzell, formerly professor of dermatology at the university and consultant of the city department of health, died in April.

Commencement at Jefferson.—The one hundred and second commencement of Jefferson Medical College was held in the Academy of Music, June 3. There were 138 graduates representing thirty-two states and foreign countries; fifty-one members of the class were commissioned as first lieutenants of the army medical officers reserve corps, and special awards were made to twenty-two. The honorary degree of doctor of science was conferred on Dr. Francis X. Dercum, emeritus professor of nervous and mental diseases, and Dr. Fordyce Barker St. John, professor of surgery, Columbia University College of Physicians and Surgeons, New York, who delivered the commencement address. The president of the board of trustees, Alba B. Johnson, conferred the degrees, and the dean, Dr. Ross V. Patterson, awarded the prizes; Major Frederick H. Mills presented the army commissions. At the annual dinner of the alumni association of Jefferson the previous day, the class of 1902 presented an oil portrait of Dr. John Chalmers Da Costa to the school. Dr. Da Costa has been on the faculty for forty years.

RHODE ISLAND

Personal.—Dr. Edward S. Brackett has been appointed chief of staff of the Providence Lying-In Hospital; Miss Edwina Porter, superintendent of nurses of the hospital, has resigned after twenty-three years of service, ten of which were as superintendent of nurses.——Dr. Isaac Gerber, Providence, has been appointed visiting radiologist to the Pondville Hospital, which is to be opened by the governor of Massachusetts, June 21, at Norfolk, for the treatment of cancer.

State Medical Election.—The annual meeting of the Rhode Island Medical Society was held in Providence, June 2, under the presidency of Dr. Herbert G. Partridge. The anniversary chairman at the annual dinner in the Biltmore Hotel was Dr. Lucius C. Kingman, Providence, and the speakers were Dr. James J. Walsh, New York, and Prof. George P. Baker of Yale University Among the scientific papers presented were "The Ketogenic Diet in the Treatment of Epilepsy in Children" Dr Fritz B Talbot, Boston, "Observations on Blood Pressure," Dr William E Preble, Boston, "Injuries of Bones and Joints in the Upper Extremity" Dr Thomas Turner Thomas, Philadelphia "What the Mind Does to the Body," Dr James J Walsh New York "Prenatal Problems," Dr Paul Appleton, "Hyperesthetic Rhinitis," Dr Francis B Sargent, and "Dentistry as the Medical Profession Sees It" Ernest S Calder, D D S, all of Providence Dr Norman MacLeod, Newport, was elected president at this meeting, Drs Arthur H Harrington, Saylesville, and Frank T Fulton, Providence, vice presidents, Dr Jesse Mowry, Providence, treasurer, and Dr James W Leech, Providence secretary The next meeting will be held in Providence, June 7, 1928 The subject of the Fisk Fund prize essay for the coming year will be "Epidemic Encephalitis"

TEXAS

University News—The east wing of the main medical college building at Galveston is being remodeled to provide space for a larger number of students and to improve the facilities for teaching Forty-six graduates of the school were awarded diplomas at the commencement exercises, May 31

Bank President Resigns to Practice Medicine—Dr Hatch W Cummings has retired as president of the Planters' and Merchants State Bank at Hearne, it is reported in order to devote more time to the practice of medicine and to his duties as president of the state board of medical examiners Dr Cummings is a past president of the Texas State Medical Association, he has served as president of the bank since 1910

VERMONT

Meeting of Health Officers—Health officers from all parts of the state met at Burlington, June 2-3 in the College of Medicine Building for the annual conference Among others, Dr Edward J Rogers spoke on Control of Water Supplies" and Tuberculosis Work in Vermont", Dr Charles F Dalton, Prevention and Control of Communicable Diseases Dr Charles F Whitney, "Health Officers' Use of the Laboratory", Dr Fred S Kent, "Venereal Diseases", Dr William G Ricker, "School Houses and School Children Dr Clarence H Burr, "The Problem of Nuisances," and Dr John [illegible] Gifford, Relation of the Health Officer to the Physicia[illegible]

WYOMING

Hospital News.—A new $125,000 hospital f[illegible] tu[illegible] patients has been completed at Basin

Personal.—Dr Thomas E Marshall [illegible] an [illegible] been appointed county health officer for [illegible] years to succeed Dr Edwin E Whedon [illegible] C Nelson Cheyenne, has been appointed h[illegible]cer of Laramie County to succeed Dr John H C[illegible]—Dr Louis A Williams, Laramie, has been appointed health officer of Albany County to succeed [illegible] Richard M Leake—Dr Victor A Mokler Th[illegible]opolis has been named state health officer for Hot Spr[illegible] County—Dr Maurice J Goldberg, Kemmerer, has b[illegible]ted health officer of Lincoln County to succeed Dr [illegible] R Marquis, Kemmerer

State Medical Meeting—The twenty fifth annual meeting of the Wyoming State Medical Society will be at Cheyenne, June 27 29, with headquarters in the Plains Hotel and under the presidency of Dr Vincent J Keating of Sheridan The meeting will be held in the Masonic Temple at Nineteenth and Capitol avenues where, Monday afternoon, among others Dr Jabez N Jackson, Kansas City, President of the American Medical Association, will give an address The house of delegates will have its first meeting, Monday afternoon followed by a smoker in the evening, Tuesday morning will be devoted to clinics, and Tuesday afternoon and Wednesday to papers and discussions Prof Charles W M Poynter of the University of Nebraska College of Medicine will speak on "Routes of Extension of Peritoneal Infection". Marcus O Shivers, Colorado Springs, "Problems of Goiter", Frederick L Beck, Cheyenne, "Sinus Problems", Water W Yates, Casper "Squint," and Archie P Kimball, Casper "Diagnosis and Treatment of Gastric and Duodenal Ulcers" Among other speakers will be Drs Arthur T McCormack, Louisville, Ky., Harold Gifford, Omaha, Albert R Mitchell Lincoln Neb, George P Johnston, Cheyenne Dr Edson L Bridges of the University of Nebraska College of Medicine will conduct a medical clinic Entertainment, as the secretary says, truly western in style, will be provided for the members and their wives One of the features will be a banquet Tuesday evening with dancing and bridge

GENERAL

American Board of Otolaryngology—At the examination of the American Board of Otolaryngology, held, May 16-17, Washington, D C, 142 men were examined, 119 of whom passed and twenty-three failed, at the examination held in Spokane, Wash, June 4, forty-six passed and six failed The next examination will be in Detroit, September 12 Applications to take the examination should be sent to Dr Hanau W Loeb, secretary, 1402 South Grand Boulevard, St Louis, Mo

Centenary of Journal Next Year.—When the former owners of the *Boston Medical and Surgical Journal* relinquished control, they incorporated the condition that the journal complete its one hundredth anniversary under its present name, that anniversary will occur next year The present management is considering changing the name of the journal then to the *New England Journal of Medicine*, and making it the official journal of the various New England states medical societies

Wild Rats and Food Poisoning.—Rats gathered at various places in San Francisco have been studied by the Hooper Foundation for Medical Research at the University of California in cooperation with the U S Public Health Service, to determine whether they are capable of transmitting bacterial disease Among 775 rats examined, fifty-eight were found infected with bacterial diseases which could be transmitted, and about 2 per cent of them carried highly virulent bacteria in their intestinal tract and were capable of infecting food by their droppings This study was aside from that of rat plague, and if the data presented pictures conditions as they are, the danger of food poisoning from rats is an important problem, particularly so in the cities in which rat eradication work is not carried on In another investigation made in Oakland by the Hooper Foundation on methods of preventing food poisoning, it was discovered there are four rat diseases transmitted by rodents in that city hem[illegible] a septicemia, plague, rat typhoid and pseudotub[illegible]

Study of Mosaic Diseases of Plants—An expedition has [illegible]turned from Africa with a collection of plants gathered lon[illegible] the west coast and in the Canary Islands by H H [illegible]Kinney, plant pathologist of the U S Department of Agriculture for a study of mosaic diseases of plants Plant scientists are engaged in developing crops that are immune to these diseases the most characteristic feature of which is the mosaic pattern caused by the green and yellow spotting of leaves of the diseased plants They cause serious losses in the potato, tomato sugar cane and tobacco, and, in some places corn and wheat crops The department of agriculture states that the virus is present in the juices of diseased plants and that it can be transmitted by insects in some cases by contact in others and by contamination of the soil in others The virus may remain active in dried specimens of certain plants for many years It cannot be seen by the best microscope now available, Mr McKinney, while on this trip, visited the laboratory of the medical research council in England to study the microscope developed by Barnard which, by means of ultraviolet rays, metallic reflectors and quartz lenses brings to view details of objects much smaller than those which are visible under the ordinary microscope

Children Under Institutional Care.—The U S Department of Commerce has issued a report which appears complete for the first time in a single volume with statistics on dependent, neglected and delinquent children in the United States as of 1923, the latest federal census of children in institutions and foster homes The report is arranged in three sections the last one dealing primarily with inmates of institutions for juvenile delinquents obtained from 145 institutions receiving children on court commitment It appears that there were, in 1923, 404,678 children in institutions or under supervision, the largest number being in institutions primarily for dependent children There is an increasing tendency, it is said, toward placing dependent children in foster homes However, 64 2 per cent of the children were found in institutions or receiving homes The number of juvenile delinquents under 18 years of age admitted to institutions in the first six months of 1923 was 12,710 Of these 2,445 were committed to jails and workhouses, and 945 to prisons and reformatories There has been a great change, the report adds, in the methods used in handling child delinquencies since 1910 A much smaller proportion is committed to penal institutions for adults, and a greater proportion to special institutions for juvenile delinquents, such as industrial and reform schools Only 54 per cent of the juvenile delinquents had been living under normal home conditions The number of children leaving institutions during the first six months of 1923 was 10,032, 73 4 per cent of whom were paroled Of those children who left penal institutions, only 20 per cent were paroled, and 46 per cent left because of expiration of sentence

Renewal of Registration Under Harrison Narcotic Act—Physicians who desire to continue to administer, dispense and prescribe narcotics must renew their registration under the Harrison Narcotic Act on or before June 30, paying the annual tax, $1 Failure to do so carries with it liability to criminal prosecution, and subjects the tardy registrant to a 25 per cent increase in the tax Registration in class IV carries with it the right to administer, dispense and prescribe narcotics generally, but does not entitle the registrant to dispense the so-called exempt preparations If the physician desires also to dispense such preparations he should register in class V as well as in class IV Registration in class V is not required of physicians who prescribe only the so called exempt preparations, but do not dispense them No extra tax is collectable for the dual registration If a physician limits his use of narcotics to the dispensing of so-called exempt preparations, he need register only in class V, in which case a tax of $1 must be paid The exempt narcotic preparations include those that do not contain more than 2 grains of opium, or more than one-fourth grain of morphine, or more than one-eighth grain of heroin, or more than 1 grain of codeine, or any salt, or derivative of any of them in 1 fluidounce, or, if a solid or semisolid preparation, in 1 avoirdupois ounce, or to liniments, ointments, or other preparations which are prepared for external use, only, except liniments, ointments and other preparations which contain cocaine or any of its salts or alpha or beta eucaine or any of their salts or any synthetic substitute for them These preparations in order to come within the exempt class must contain active medicinal drugs other than narcotics, and must be used as medicines and not for the purpose of evading the provisions of the act

Airplanes and Ships in Flood Relief Work—The old custom of relying on the army for stores in time of disaster was followed in the Mississippi flood When the overflow began, April 4, the governors of Mississippi and Louisiana requested tents from the army for refugees, the supply forwarded was augmented again, April 19, by 1,000 tents from the army storehouse at St Louis, by several hundred from the storehouses at Chicago and Fort McPherson, Georgia, and by 5,000 from the Philadelphia depot, 2,500 from Fort Omaha, three carloads of tent poles and pins from Philadelphia, and 204,000 tent pins from Columbus, Ohio The War Department placed at the disposal of the Red Cross, April 22, 1,435 wall tents, 16,207 pyramidal tents, 11 102 cots, more than 27,000 blankets, and five hospital tents The next day the Philadelphia depot sent 3,310 additional tents A few days later, army ranges and cooks were sent to the camps, and government boats and barges began rescuing the inhabitants By May 4 the army had seventeen airplanes photographing levees, locating marooned refugees, landing engineers, carrying messages and delivering emergent supplies The navy sent its first seaplane to the flooded area, April 17, later sending thirty-six other planes which performed excellent service under adverse flying conditions The navy also dispatched radio operators from Pensacola A radiogram sent from Bruin, Ark, for example, to the Red Cross headquarters at Memphis, stated that an epidemic had occurred among the refugees and that no medical aid was available Within an hour physicians had been transported to the camp and were administering to the sick The navy contributed the ships, *Allegheny* and *Bagaduce,* from Key West, which transported supplies and refugees on the river while smaller craft were detailed elsewhere The U S Treasury Department contributed every vessel of the coast guard fleet that could be used for rescue and relief in the flooded area, at the time of this report in the *Red Cross Courier,* the fleet comprised fifty power surf boats, twenty-two patrol boats, fourteen smaller craft, nine picket boats, four cutters and three harbor cutters, all manned by 603 officers and men The coast guard force won much praise for their work

Society News—At the annual meeting of the Associated Anesthetists of the United States and Canada, Washington, D C, May 16-17 Dr John H Evans, Buffalo, was made president, Dr Ralph M Waters, Madison, Wis, president-elect, Drs Wilmer Baker, New Orleans, Harold A Thompson, San Diego, Edward Leslie Burwell, New Rochelle, N Y, and John A Blezard, Edmonton, Canada, vice presidents, and Dr F H Hoeffer McMechan, Avon Lake, Ohio, secretary ——Dr Samuel W Welch, state health officer of Alabama, was elected president of the Conference of State and Provincial Health Authorities of North America at the recent annual meeting in Washington ——At the annual meeting of the American Neurological Association, May 26, Dr Charles L Dana, New York, was elected president, Drs Bernard Sachs New York, and Adolf Meyer, Baltimore, vice presidents, and Dr Henry A Riley New York, secretary-treasurer The next meeting will be held at Washington in May, 1928 ——At the annual meeting of the American Urological Society, Baltimore, May 23-25, Dr Richard F O Neil, Boston, became president of the society, Dr Homer G Hamer, Indianapolis, was made president-elect, and Dr Alexander Randall, Philadelphia, was elected secretary The next annual meeting will be in Chicago ——At the annual meeting of the American Climatological and Clinical Association, May 23 27, White Sulphur Springs, W Va, the following officers were elected for the ensuing year president, Dr Joseph H Pratt, Boston, vice presidents, Drs James S McLester, Birmingham, Ala, and George D Porter, Toronto, Ont, secretary-treasurer, Dr Arthur K Stone, Framingham Center, and recorder, Dr Cleveland Floyd, Boston The next meeting will be held at Washington, D C, May 1-2, 1928 ——Dr Sidney Yankauer, New York, was elected president of the American Bronchoscopic Society at the annual meeting, May 21, Atlantic City, N J, and Dr Louis H Clerf, Philadelphia, secretary ——Dr Joseph Brettauer, New York, was elected president of the American Gynecological Society at the annual meeting held in Hot Springs, Va, May 23-25, and Dr Floyd E Keene, Philadelphia, secretary The next meeting will be held at Washington, D C, April 30-May 2, 1928 ——Dr Adolf Meyer, Henry Phipps professor of psychiatry, Johns Hopkins University Medical Department, and director of the Phipps Psychiatric Clinic, Baltimore, was elected president of the American Psychiatric Association at the annual meeting in Cincinnati, June 3, and Dr Earl D Bond, Philadelphia, secretary The next meeting will be held at Minneapolis in 1928 ——Dr G Kirby Collier, Rochester, N Y, was elected president of the National Association for the Study of Epilepsy at the annual meeting held, May 31-June 1, at Cincinnati, and Dr Arthur L Shaw, Utica, N Y, secretary ——Dr D Bryson Delavan, New York, was elected president of the American Laryngological Association at the annual meeting, Atlantic City, May 23-25, and Dr George M Coates, Philadelphia, secretary ——The American Dietetic Association will hold its tenth annual meeting, October 17-19, at St Louis, with headquarters at the Hotel Statler

FOREIGN

World Population Conference—The first World Population Conference will be held in the Salle Centrale, Geneva, Switzerland, August 31-September 2, to consider the question of population growth from an international point of view Among the subjects to be discussed are population and the food supply, the biology of population growth, optimum density, the differential birth rate, migration and its control and fertility and sterility in relation to population Sir Bernard Mallet is chairman of the council of the conference, which includes about twenty-four scientists of France, England and Germany, Australia, Holland, Switzerland and the United States, the members from the United States being Drs William Whitridge Williams, Raymond Pearl, Wesley C Mitchell, Clarence C Little, Prof Henry P. Fairchild and Prof. Edward M East

International Congress of History of Medicine.—The Sixth International Congress of the History of Medicine will be held at the University of Leiden, Amsterdam, July 18 23, under the patronage of the Prince of the Netherlands, and with a number of government officials as honorary presidents There will be a visit to the exposition of physical instruments made by Dutch scientists in the eighteenth century, and moving picture illustrations of researches of Van Leeuwenhoek and Swammerdam, a visit to The Hague and Scheveningen, a reception by the Society of Physicians of The Hague, a visit to the medico-historic exposition of the Museum Suasso, and a reception by the mayors and municipalities of Amsterdam and Leiden Among the speakers will be Drs Crommelin and Nuijens Dr J G De Lint is president of the executive committee

New Coroner's Act Important Changes to Come into Force

A new coroner's act makes several important changes The appointment of county or borough coroners and of their deputies or assistant deputies is restricted to lawyers or physicians of not less than five years' standing The right of a coroner to hold an inquest without a jury is maintained, but the cases in which a coroner must summon a jury have been extended to include infanticide, death caused by an accident, poisoning or disease, notice of which is required to be given to a government department or inspector or under any act, death resulting from a street accident caused by the use of a vehicle, and where death has occurred in such circumstances that their continuance or recurrence is prejudicial to public health or safety The coroner may also summon a jury in other cases if he thinks it necessary He must still view the body, though the jury need not unless the coroner so directs or a majority of the jury desires to do so Where a coroner is informed, before the jury has given its verdict, that some person is charged with the murder, manslaughter or infanticide of the dead person he shall, in the absence of reason to the contrary *adjourn the inquest until* after the conclusion of the criminal proceedings and may discharge the jury If the coroner then resumes the adjourned inquest, no inquisition shall charge the accused person of any offense of which he could have been convicted on the indictment or contain any finding inconsistent with those proceedings Where a coroner's inquisition charges a person with murder manslaughter or infanticide the coroner has the same power as examining justices of committing that person for trial, but authority is given to the lord chancellor to make rules regulating the practice and procedure when persons are charged by a coroner's inquisition with those offenses An important provision of the act is the power given to a coroner in certain cases to direct a physician to hold a necropsy if he thinks that such examination may prove an inquest to be unnecessary The fees payable to a physician under the act are $7 50 for each day on which he is required to attend an inquest as a witness, $10 for making a necropsy, and for making that and attending to give evidence, $15 for the first day and $7 50 for each subsequent day of attendance

Shall We Become Supermen?

In the *Evening News* Sir Arthur Keith, with all his usual force, lucidity and charm discusses the fascinating question whether we shall become supermen He first refers to the ample evidence of improvement in body and brain in the advance of man from apedom But this advance has never continued along a straight, *unbroken line, everywhere there* are zigzags and breaks As far back as we can go we find the world inhabited by different breeds of men and in these breeds no two individuals are alike Such differences and the zigzaggedness of the course makes it difficult to say whether mankind as a whole is progressing unless one surveys *long* periods It was toward the close of the ice age that men and women of our own kind first appeared in Europe Many of the men were tall and large brained—as tall, strong, and well equipped in head and heart as any living race But not all were tall and big headed, many were the opposite, the women, in particular were short of stature The people of modern Europe are not superior to these early pioneers in strength of limb or innate capacity of mind Keith recently had an opportunity of examining the skulls and skeletons of men and women who abode in Ur of the Chaldees long before the time of Abraham The men were big-headed with robust faces, they were the founders of our earliest civilization—men of enterprise and erudition Their descendants are wandering Arabs of the desert today Five thousand years ago the *Egyptians were building pyramids*, in their governing and upper classes, as we know from examination of skulls, there were many fine men—men no whit behind the best we can show today, and better, Keith thinks, than can now be found in Egypt among their descendants We do not know much concerning the cranial capacities of the ancient Greeks, but it is difficult to believe that the population of modern Greece has their equal No one can survey collections of skulls that represent the upper classes of ancient Rome in her most prosperous periods without being impressed by the liberal lines on which nature had framed them Modern Italy would be hard pressed to show their like

One cannot study records of ancient Babylonia, Egypt, Greece and Rome without a note of alarm Civilization seized them and sooner or later left them exhausted And in these times civilization has spread into and seized the wide virgin field of western Europe, of which we form part Will the fire of civilization consume us also? In our conception of empire Keith finds our chief hope It gives scope for our energies There is no sign of weakening anywhere Our racial flag has been firmly planted on wide continental spaces, the United States Canada, South Africa, Australia, and New Zealand are held by men of the western European stock, British blood predominates Our race establishes itself in the world more and more firmly, its prospects continue to improve, we increase rapidly in numbers, but do we improve in quality? Babylonia, Egypt, Greece and Rome did not fail for lack of children, but for a dearth of children of the right kind Civilization exposes the ablest of her votaries to the temptation of luxury The basal and essential condition for racial progress is a healthy birth rate in every grade of the community As we raise our standard of living, the maintenance and education of children becomes more expensive, we become more and more tempted to spend on ourselves what should be sacrificed in raising another generation The most alarming circumstance Keith sees today is the steady rise in the cost of 'higher education The pursuit of wealth and the ambition to climb the social ladder, although they serve as driving powers in every form of civilization do not tend toward racial betterment Civilization is a winnowing process, and those who survive its ordeal are not our intellectuals and philosophers—our men of superior endowment—but the plain men imbued with the instincts of primitive humanity a zest for life and for children The right name for the tower of Babel is civilization, every attempt to build it has ended in the confusion of the builders Can we, by taking thought, avoid former errors? Keith thinks we may, but the fact remains that there were as highly endowed men and women in the cities of the plain *6,000 years* ago as *there* are in New York today

Another aspect of the problem of human progress is of surpassing interest Not many generations ago our forefathers were hunters and lived on what they could kill or gather Today we have the produce of the world at our disposal and most of us can afford to eat to repletion Earlier generations lived half naked in the open, we clothe our bodies and live in warm houses We are passing through a great experiment how will our bodies emerge from it? Disorders of digestion are rife appendicitis becomes alarmingly prevalent, our teeth tend to erupt in a disorderly fashion and are *prone* to disease, and we become more and more rabbit-mouthed In the inhabitants of England in former times, caries of the teeth and contractions of the palate hardly occurred until the eighteenth century and then they are found plentifully in the skulls. There is evidence of other physical changes. We cannot say that as a people we are growing stronger, taller or bigger brained. Our modern ways of living are having an effect on our constitution, but Keith sees no reason to fear these changes. As our knowledge of the human body increases we shall learn how to avoid them. Some think that man has reached the highest point of evolution and that he has become a fixed and stable type. But nothing can live and be stable; change may be exceedingly slow, but it is inevitable. Man cannot escape from this universal law; he must change, for better or for worse. In the world today we see changes proceeding apace; some races are dying out, others are taking their place. One would like to think that "every day, in every way" we are getting better and better. Our ideals are higher. Our opportunities of living life to the full continue to improve. But we cannot claim to be physically better or higher than the men who founded civilization 6,000 years ago. However, when we go back further and see man emerge from a form little higher than an ape and reach his present estate, the hope wells up that in some way we may yet circumvent the limitations of civilization and rise to the status of superhumanity.

Women Liberals Favor Birth Control

The question of birth control was discussed at the annual council meetings of the Women's National Liberal Federation. A motion in the name of Mrs. Spring Rice declared that a national policy on such matters as emigration and birth control was urgently required, and stated that "while emigration can be only a temporary cure for overpopulation and, by its process of selection, may be a danger to the country, scientific birth control provides a means of increasing the efficiency of the nation." Mrs. Spring Rice said that the time had come when liberalism should bring into its political thought two grave questions which had a profound effect on the population of the country. It was not for the good of the empire that we should send our best young men and women to the dominions. As to birth control, she wanted it to be associated not with the limitation of families so much as with the improvement of families. Lady Acland, seconding, said that the resolution was a call from the womanhood of the land to the nation to formulate a policy about the ever-present question of population. We were bringing down the death rate and were asking at the same time for a more responsible parenthood. There were persons who were shocked that mothers should be able to choose how many children should be brought into the world. We could leave that to the generation that looked on population as cannon fodder. There was no doubt that the great majority of married women did, in some form or other, practice birth control, but owing to lack of knowledge it was not the most rational form. Mrs. Walter Runciman moved as an amendment that "inasmuch as there is no general consensus of scientific opinion on the subject of birth control and the question has given rise to deep-rooted differences of opinion on social, moral and religious grounds, it is undesirable to include a pronouncement on the subject in the policy of this council." The amendment was defeated and the resolution adopted. The conference then adopted a resolution, moved by Lady Howarth and seconded by Mrs. N. Barclay, that information should be available to those who asked for it at the centers controlled by the ministry of health, where the physicians were in possession of the medical history of the mothers and knew to whom such information should be given, "by this means enabling the poorest members of the community to obtain information to which the wealthier classes already have access."

The Diagnosis of Tuberculosis

Professor Bard, following the congress held in Lyons, has published an outline of the question of diagnosis of pulmonary tuberculosis. Two contrary tendencies may be noted. Physicians for sanatoriums, insurance companies or military recruiting are bent on not letting any suspect escape who might benefit by early treatment or who might later develop the disease and reflect on their diagnostic skill. Therefore, many persons are declared suspects who are not tuberculous and never will be, or who are carriers of bacilli that will always remain latent France pays, every year, immense sums, in the form of pensions, to ex-service men declared "suspects" by examining boards but who are today in excellent health, having given only vague signs of pulmonary sclerosis on fluoroscopy. The pension law declares that a pension right once acquired shall be retained irrespective of later developments. The societies of pensioned soldiers now play an important political rôle in the parliamentary elections. On the other hand, physicians in hospitals and dispensaries, having had their attention directed to the large number of persons previously declared "suspected" who never develop tuberculosis, are now inclined to refuse to accept a diagnosis of tuberculosis except on explicit proof, which is frequently unobtainable. They hesitate to apply isolation, the loss of employment, and the consequent renunciation of future prospects, to all subjects officially recognized as tuberculous. Bard, in concluding, takes frankly the part of the latter.

The Hygienic Service and the Public Health Service in Morocco

The organization in Morocco of the hygienic service and of the public health service, in their present form, is of recent origin. In March, 1926, Dr. Colombani was appointed general director, with full power and a centralization of all the services in his hands. This concentration of authority in a single man is the principle that constitutes not only the newness but also the efficacy of Moroccan organization. Efforts are directed toward supplying medical aid for both Europeans and natives, toward the organization of general hygiene, prophylaxis on a large scale, and the hygienic education of Europeans and natives. There have been built five large European hospitals, nine regional hospitals for both Europeans and natives, 130 infirmaries for the natives, and maternity hospitals, some for Europeans and others for natives. Furthermore, a colonial medical service makes it possible to give to the colonists (even those living most remote from the centers) and to their families the necessary medical aid. The supervision of hygiene and the general prophylaxis of epidemic diseases is accomplished in the cities through the hygienic bureaus, of which there are at present eleven. The "*groupes sanitaires mobiles*" are the distinctive and original feature They not merely constitute a mobile dispensary for consultation, but on the outbreak of an epidemic, they can be enlarged to form an organization for prophylactic defense. Particular attention is paid to the prophylaxis of plague, typhoid, smallpox, syphilis, tuberculosis, trachoma and malaria. Antisyphilitic dispensaries have been established in all the important cities, and arsphenamine treatment is actively propagated among all groups of natives. In order that the native population may understand the importance of the measures imposed on them and the value of the care and treatment offered them, the physicians constituting the mobile sanitary groups all speak the language of the country and act as instructors. In addition, a Mussulman who has studied in France is employed to make the rounds of the cities and rural communities and to give talks on hygienic and health topics. Parallel with that, a publicity campaign is conducted with a view to instructing the European colonists.

The Sterilization of Drinking Water by Electricity

The sterilization of drinking water by electrical procedures is coming more and more into use in France and may become the predominant method, especially where waterfalls make cheap electric power available. The construction and maintenance of aqueducts from new sources of water located at long distances is becoming increasingly expensive. The region of Nice and the Riviéra is supplied today almost entirely with water thus sterilized, and many other cities are adopting the method. Avignon, which, formerly, after every high water on the Rhone, experienced an epidemic of typhoid, has introduced the system and there has not been a case of typhoid since that time. Dinard, a region of Bretagne in which infection has been common, and Soulac, on the coast of Gascony, have done the same. Lorient, a fishing port, after suffering several outbreaks of typhoid, is now sterilizing with ozone the waters of the Scorff and the Scave. Auray consumes the muddy and contaminated waters of the Tregurey river after being purified and clarified by means of ozone. Especially the cities frequented by French and foreign tourists have been the first to adopt the system, in order to prevent the spread of reports unfavorable to their business; also cities having large military garrisons, which, as is well known, constitute a favorable environment for epidemics. Brest, Toulon, Saint-Brieuc, Paramé, Saint-Servan, Dinan, Avranches, Angouléme, Cognac, Granville, Chatellerault, Laval, and many cities of the lower Seine, are now supplied exclusively with ozonized water, as a consequence of which their sanitary condition improved at once. From calculations made it appears that the cost of the process ranges, according to the place, between 1 and 2 centimes per cubic meter of water, and in some instances in which the sources of the electricity are near at hand and a proportionate low rate prevails the cost has been brought considerably below 1 centime per cubic meter. The city of Paris is studying the question of cost at present with a view to introducing the system if feasible.

Congress of the German Society of Internal Medicine

The congress of the Deutsche Gesellschaft fur innere Medizin was held at Wiesbaden, April 25-28, 1927. The first day of the congress, which was presided over by Professor Naegeli of Zurich, was devoted to psychotherapy. The principal paper was presented by Gaupp of Tubingen. He emphasized in psychotherapy the value of the unity of the body and the psyche, and the significance of psychologic research for the field of medicine. Psychotherapy is an ancient mode of treatment. As a special science, however, which passes from intuition to conscious endeavor, it is new. Psychic impairment and disturbed bodily function may be in close mutual relation. The effects of pathologic psychic processes, which are often only accentuations of normal processes, on body and mind may be referred to as psychogenic. In a special state of consciousness such as hypnosis, the action of the psyche affects the body more deeply than does the will when consciousness is clear and unimpaired. For example, in a hypnotic state, symptoms the cause of which is not clear may be relieved if the patient recalls the events that produced them in the first instance. Hypnosis has been supplanted by the introduction of Freud's psychanalysis, in which the central idea is the conception of the effect on the waking ego of perceptions and feelings that have been banished, by an effort, from consciousness. At first Freud thought that in the sexual injuries of childhood he had discovered the sole cause of neuroses. Later, he laid the chief emphasis on an abnormal sexual constitution. The ideas associated with this conception (Oedipus complex, suppression, etc.) and the resolution and elimination of the complexes through the psychanalysis of perceptions of which the subject was previously unconscious are well known. The author called attention to the fact that the accentuation of sexual ideas (sexualism) has elements of danger for the patient. Some of Freud's pupils are departing from the teachings of the master. Jung amplifies the notion of the libido into the conception of the psychic productive power. Steckel varies the form of treatment and recommends what he terms a "*schnellanalyse,*" or quick analysis. Ludwig Frank and others have clung to the old method of "psychocatharsis." Alfred Adler, plainly under the influence of Hobbes and Nietzsche, develops the theory of the origin of neuroses through the conflict between a dominant will and an inferiority complex that is based on congenital or acquired organic defects. From such conflict there results for every neurotic the chief guiding motive of his life, and the neurosis becomes for the patient a mere escape symptom. Freud and Adler as well trace every neurosis back to early experiences in childhood. They both make the mistake of allowing themselves to make dogmatic generalizations on the basis of single observations, valuable though they may be. Experience teaches that the majority of neurotic patients cannot be cured by analysis and enlightenment alone. In addition to the analysis of the personality recourse may be had to "psychagogics," whereby the patient is led to set a worthwhile goal for himself in life. In that connection, the development of group consciousness is essential. The simpler forms of neurotic disorders can be improved or cured by various methods of suggestive treatment. Often, however, a cure is impossible, owing to inborn pathologic dispositions, so that a neurosis may be the relatively best escape from a sad but unavoidable life situation. Hypnosis has lost its significance because recurrences are frequent. The author gave a survey of the other forms of suggestive treatment, and discussed the injuries to which patients were exposed by wrong methods of psychotherapy. He explained also the demands made by psychanalysts with respect to the training of psychotherapists. Gaupp stated further that the observations of the recent war furnish evidence that not all neuroses are traceable to childhood experiences. As supplementary to the analysis of personality, he emphasizes the value of "therapeutic pedagogics" and insistance on ethical teachings; more particularly, the overcoming of selfishness. In closing, he raised the question as to whether psychotherapy was applicable to a group of persons, to certain strata of the population, or even to a whole people, and, in that connection, called attention to the deep effects that the psychic derangements of the war and the weakening of religious ties had had on the population. However, a detailed knowledge of the individual psyche constitutes the basis for a knowledge of the group, and it is very evidently the duty of the physician to minister, in all wisdom and kindness, to the needs and sufferings of individuals. (An almost complete reprint of Gaupp's paper will be found in the *Deutsche medizinische Wochenschrift* 53:807 [May 6] 1927.)

According to Fleischmann of Nassau, psychotherapy covers more than treatment by means of psychanalysis. The preconditions for psychotherapeutic intervention are a careful examination of the patient and certainty of diagnosis, which many psychotherapists make the mistake of regarding as of secondary importance. Psychotherapeutic methods may be divided into two distinct classes, the secret primitive unsystematic procedures and the systematic modes of operation; some are lacking a theoretical basis, as hypnosis, suggestion, "psychagogics" and "therapeutic pedagogics," while psychanalysis and Adler's *"individualpsychologie"* have a theoretical substratum. The successful results secured with psychanalysis are probably referable to their suggestive effect, for which reason it is recommended as a "rational anamnesis," which helps the patient to understand the connections in the development of his disorder and stimulates him to active cooperation in overcoming it. The dangers in the practical application of psychanalysis are associated with the facts that things of which the patient is blissfully unconscious are sometimes brought into the foreground of consciousness in such a manner as to work a positive injury to the patient and that the sexual factor often receives undue emphasis. Then, too, the interplay of emotions as between the physician and the patient has its dangers. The physician who applies psychanalytic treatment must remain conscious of the fact that in very few cases does he effect a causal cure. He can, however, if he retains a clear conception of a feasible objective, achieve good results in many cases of practical medicine and thus find psychotherapy a valuable aid in the treatment of bodily disease as well.

During the discussion that followed, Römheld (Hornegg o. N.) dealt with psychotherapy as applied to internal diseases. He employs a method that he has found useful in many cases. It consists in endeavoring to direct a patient's attention away from the organ or organs that are diseased to another organ that is not diseased.

Eight Hundred and Sixty-Six Abortions Performed by a Bessarabian Physician

The director of the state hospital in Kishenew, the capital of Bessarabia, was struck by the great number of women admitted to the gynecologic section of the hospital, with conditions pointing to preceding abortion. He asked the police to investigate, and the result was the revelation that apparently Dr. Stephan Bolinsky, a physician in Lapusna, has performed criminal abortion in a commercialistic manner. His house has been searched and secret records point to the implication that he performed criminal abortion in 866 instances. Almost all his instruments consisted of those necessary to the performance of abortion. In his office were many embryos kept in alcohol and in the cellar were found a great quantity of small bones which seem to have been derived from embryos. The physician, his midwife and his nurse have all been arrested. The disclosure has aroused surprise in medical circles since Dr. Bolinsky was known as a good gynecologist, who pursued his specialty in a scientific manner, having written many valuable articles on gynecologic subjects. He denies the crime imputed to him and states that the bones in the cellar are of dogs. The county court in Lapusna will try the case in June, and more than 200 witnesses and five medical experts have been summoned for the trial.

Bill Relating to Venereal Diseases

The Roumanian government has sent out a special committee to study the fight against venereal diseases in different nations of western Europe. The committee spent several weeks in Vienna, Berlin, Paris and London, and its experiences are embodied in a new bill. In drafting the bill an endeavor was made to copy the German system, which is most suitable for Roumanian conditions. According to the bill it is the right and duty of every infected person to have himself treated. His right to treatment he may realize in the dispensaries of the national sickness insurance organization. His duty to have himself treated may be enforced by law. He must be treated by a qualified physician, or if it is suspected that he has a venereal disease and that he is disseminating it, the local health magistrate may demand a medical certificate of his condition, or may subject him to an examination made by an official physician. Furthermore, a patient with venereal disease must be informed that he is suffering from a contagious malady, and to this end every physician is obliged to give an explanatory leaflet to all his patients who are commencing a course of antivenereal treatment. It was suggested also that cured patients should be given a leaflet instructing them how to protect themselves against a fresh infection. This system proved efficacious in Sweden. Treating patients by correspondence is forbidden. The bill prescribes punishment for those who knowingly have their syphilitic babies nursed by a healthy woman. The bill contains a paragraph according to which physicians are obliged to report to the nearest venereal station their patients who refuse to undergo treatment. In case of continued delinquency the station must report the patient to the health magistrate. The bill dropped compulsory notification of the names of patients with venereal disease. The opponents of reporting the names of patients argued that this would bear hardest on those who were willing to have themselves treated conscientiously, and would deter many patients from calling on physicians.

History of Public Health Administration in Roumania

At a recent meeting of the medical association Dr. N. N. Saveanu, late minister of health, gave a little sketch of the history of public health administration. He said that the first public health institutions were the cloisters. Some records, dating back to the sixteenth century, state that sufferers have sought relief for their bodily and mental disorders in the cloisters of the monks. This primitive arrangement was perfected at about the beginning of the nineteenth century. The real basis for public health organization was laid, however, as late as 1874, by the so-called Davila law. Under this the first public health law of Roumania, the physician is subordinate to the county prefect and city mayor. The appointment and dismissal of physicians at this time was the discretional right of the county and city councils. The new law of 1881, as a proof that it regarded the sanitation of rural districts as of equal importance with that of the city, transformed the old cloisters into hospitals and employed monks and nuns as nurses. The law of 1885 released physicians from local authority and enacted that they shall be appointed by the minister of internal affairs under royal decree.

With regard to the fact that the overwhelming majority of the Roumanian population are village dwellers, the government promoted the sanitation of rural districts by new laws in 1893, 1898 and 1906. In 1906, thirty-two village hospitals were erected and a new law was enacted that all hospitals should be managed by the state. All health districts were obliged to erect central hospitals. Nov. 4, 1923, a great step was taken in the progress of sanitation, the ministry of health being established.

The Obligation of Producing Medical License to Marriage

The provincial council in Zagreb, the capital of Croatia, a province of Jugoslavia, has passed a law which requires that every man who is to be married must be examined by a medical officer. The man must be of mature age and shall not suffer from tuberculosis, venereal disease, trachoma or malaria. No priest or clergyman is allowed to perform the ceremony for parties who fail to produce such certificates. In case a medical officer diagnoses a disease that may interfere with married life or may be detrimental to the offspring, he is obliged to call the attention of the parties to this fact and take up the matter with the provincial council. Both health officer and priest are responsible for observance of this law.

Marriages

Frank W. Milward, Jr, Cleveland Heights, Ohio, to Miss Norma Christine Koch of Lakewood, June 15.

Virgil Leroy Payne, Greenville, Miss, to Miss Ella Hunt Howell of Pine Bluff, Ark, April 19

Zeno Nicholas Korth, Rochester, Minn, to Miss Agnes Morton of Omaha, May 18.

Leo H Salvati, Westfield, N. J, to Miss Doris Lambrusken of Somerville, June 1

Louis Cohen to Miss Eleanor Speiser, both of Philadelphia, June 1

Deaths

Ralph Wentworth Jackson ⊕ Boston, Long Island College Hospital, Brooklyn, 1892, member and past president of the American Proctologic Society; for three years on the executive committee and chairman of the Section on Gastro-Enterology and Proctology of the American Medical Association, 1924-1925, on the staffs of the Fall River General Hospital and the Union Hospital, Fall River, St Luke's Hospital, New Bedford, Mass, and the Carney Hospital, Boston, aged 58, died, May 22, at the Garfield Memorial Hospital, Washington, D C, of acute dilatation of the heart

Charles Teackle Carter Buckner ⊕ Captain, M C, U S Army, Fairfield, Ohio, University of Maryland School of Medicine, Baltimore, 1899, commissioned a captain in 1920, served during the World War; aged 49, died, February 19, at Selma, Ala, of skull fracture received in an airplane crash

Robert William Eaton, Phoenix, Ariz ; Northwestern University Medical School, Chicago, 1915, member of the Arizona State Medical Association, served during the World War, on the staff of St Joseph's Hospital; aged 36; died, May 6, as the result of burns received in an explosion.

James Elmo Smith ⊕ Saint Jo, Texas, University of the South Medical Department, Sewanee, 1908, member of the Oklahoma State Medical Association, aged 43, died, in May, at a hospital in Gainesville, of injuries received in an automobile accident

James Hamilton Maxwell, Oklahoma City, Okla ; Memphis (Tenn) Hospital Medical College, 1901, University of Louisville School of Medicine, 1903 member of the Oklahoma State Medical Association, aged 53, died, May 5, of acute nephritis

Charles Cornelius Shope, Des Moines, Drake University College of Medicine, Des Moines, 1894 member of the Iowa State Medical Society; formerly a druggist; on the staff of the Lutheran Hospital, aged 61, died March 30, of cerebral hemorrhage.

Frederick Augustus Grazer, Sacramento, Calif , Cooper Medical College, San Francisco, 188[illegible], member of the California Medical Association for sixteen years pharmacist to the Sacramento Hospital, aged 70, died, recently, of pneumonia

Aaron Schloss, San Francisco, University of Pennsylvania School of Medicine, Philadelphia, 1883; member of the California Medical Association, aged 65, died, April 30, at his home in Berkeley Calif., of uremia

Thomas Hicks Pleasants ⊕ Lewistown, Mont ; Medical College of Virginia, Richmond, 1877; city health officer; past president of the Fergus County Medical Society; aged 70; died, May 16, of pneumonia

T. E. Pennington, Naylor, Ga ; Atlanta Medical College, 1886; member of the Medical Association of Georgia; aged 70; died, May 9, at a hospital in Valdosta, of cerebral hemorrhage

Horace Morton Leach, Rochdale, Mass ; Hospital College of Medicine, Louisville, Ky., 1876; member of the Massachusetts Medical Society; aged 83; died, May 11, of myocarditis.

William B. St. John, Bristol, Tenn.; Hospital College of Medicine, Medical Department Central University of Kentucky, Louisville, 1886, aged 61; died, May 12, of heart disease.

Paul Ralph Sigel, Detroit; Detroit College of Medicine and Surgery, 1913; aged 37; died, March 15, of cerebral hemorrhage and skull fracture received when he fell down stairs.

Lorenzo Miller Nickerson ⊕ Remsenburg, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1896; aged 57; died, May 21, of carcinoma of the bladder.

Nathaniel McClinton, Jensen, Fla.; Victoria University Medical Department, Toronto, Ont., Canada, 1865; aged 90; died, May 22, at Saginaw, Mich, of chronic myocarditis.

William Howard Gallagher, Boston; Harvard University Medical School, Boston, 1896; member of the Massachusetts Medical Society, aged 52; died, May 11, of myocarditis.

Louis W. Toles ⊕ Orlando, Fla.; Rush Medical College, Chicago, 1897; aged 64; died, May 4, at the Orange General Hospital, of uremia and chronic nephritis.

Adolph Jaenicke, Clinton, Iowa; University of Würzburg, Germany, 1879; member of the Iowa State Medical Society; aged 72, died, May 19, of angina pectoris.

Thomas J. MacFarlane, Brooklyn; Medical Department of Columbia College, New York, 1886; aged 61; was found dead in bed, May 20, of cerebral hemorrhage.

Luke Edward Bartley, Providence, R. I.; Medical Department of the University of the City of New York, 1891; aged 62, died, May 16, of heart disease.

Rose Kidd Beere, Washington, D. C.; Northwestern University Woman's Medical School, Chicago, 1892; aged 68; died, May 19, of chronic myocarditis.

Joseph Herbert Robison, Bradford, Pa.; University of Buffalo (N Y.) School of Medicine, 1895; aged 55; died, May 16, of carcinoma of the throat.

Simon Bothwell Fraser, New York; McGill University Faculty of Medicine, Montreal, Que., 1907; aged 47; died, May 19, of cerebral hemorrhage.

William T. Medling, Dyer, Tenn.; University of Nashville Medical Department, 1874; aged 77; died, March 28, of arteriosclerosis and myocarditis.

John William McKoan, Worcester, Mass.; Harvard University Medical School, Boston, 1894; aged 53; died, May 4, of acute dilatation of the heart.

Jennie Garrison Gkrist ⊕ Los Angeles; Keokuk (Iowa) Medical College, 1898 aged 57; died, May 5, at her home in Glendale, Calif., of carcinoma.

George W. Suddard, Hayti, S. D.; Bennett Medical College, Chicago 1906 aged 61; died, April 29, of injuries received in an automobile accident.

Benjamin F. Phillips, Baltimore; University of Maryland School of Medicine, Baltimore, 1878; aged 72; died, May 25, of heart disease

Alpheus W. Gregg, Kennett Square, Pa ; Hahnemann Medical College and Hospital of Philadelphia, 1889; aged 60; died, March 9.

James H. Chipman, Georgetown, Del.; Medico-Chirurgical College of Philadelphia, 1898; aged 48; died, May 9, at a local hospital

Moses E. McCray, New Albany, Kan.; American Medical College, St Louis, 1880; died, May 7, at a hospital in Kansas City, Mo

Reine Keelor Hartzell, Oakland, Calif.; Jefferson Medical College of Philadelphia, 1902; aged 47; died in May, at Los Angeles.

Alfred B. Hart ⊕ Owatonna, Minn.; University of Minnesota Medical School, Minneapolis, 1903; aged 58, died, May 10

Hubert A. Pinault, St. Joseph, Minn., Laval University Faculty of Medicine, Montreal, Que., 1883; aged 72; died, May 21.

Emil J. Merki, Chicago; University of Illinois College of Medicine, Chicago, 1902; aged 49; died, May 24, of Hodgkin's disease.

Frank T. Turner, White Hall, Md.; College of Physicians and Surgeons, Baltimore, 1879; aged 69; died, April 30.

James N. Montgomery ⊕ Chicago; Missouri Medical College, St. Louis, 1875; aged 77; died, May 22, of myocarditis

Porter K. Dobyns, Franklin, Ind.; Medical College of Indiana, Indianapolis, 1879; aged 68; died recently.

Pleasant M. Hawkins, Arp, Texas (licensed, Texas, under the Act of 1907); aged 70; died, March 21.

The Propaganda for Reform

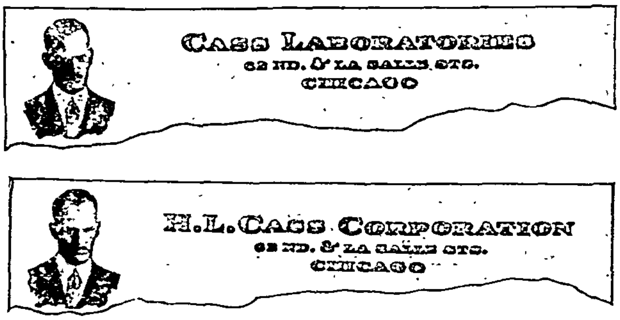
In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

THE "CASS TREATMENT" TRICKERY

In this department of The Journal, Jan. 15, 1927, under the title "Cass Treatment for Rheumatism," there was described a particularly bold piece of Chicago mail-order quackery, conducted under the name "Cass Laboratories." In this article it was shown that there was a close community of interest between this humbug and a fake "epilepsy cure," exploited under the trade names "Western Medical Association" and "Vernon Laboratories."

The article brought out the fact that the Cass Laboratories were not laboratories; that its alleged president, "Harvey L. Cass," who was featured throughout the advertising, did not exist but that the concern was run by one H. L. Cassel, in association with his brother-in-law, one Joseph V. Creevy.

In the Cass Laboratories' advertising, the mythical H. L. Cass was played up as a human interest element, his picture appearing on most of the stationery and other advertising paraphernalia. Cassel even went so far as to publish a photograph of three small children—"Tom, Bob and Dick"—said to be the children of H. L. Cass. Even a "Mrs. Cass" was dragged into this crude quack hunt for victims.



CASS LABORATORIES
62 NO. & LA SALLE STS.
CHICAGO

H. L. CASS CORPORATION
62 NO. & LA SALLE STS.
CHICAGO

To avoid the issuance of a fraud order debarring from the United States mails the quackery exploited under the name "Cass Laboratories," H. L. Cassel, the head quack of the concern, sent in a sworn statement to the government that the "Cass Laboratories" had "been discontinued and abandoned" and would not be resumed. The same quackery is now being conducted under the name "H. L. Cass Corporation," a change of name but not of business that was effected at least a month before Cassel sent in his affidavit.

The Journal article described in detail the misleading and quackish character of the claims made for the alleged treatment, and published the analysis made of the nostrum by the A. M. A. Chemical Laboratory. The "treatment" consisted of baking soda tablets, of other tablets containing aspirin and cinchophen, and of some flavored epsom salt.

In October, 1926, the Post Office Department called on the Cass Laboratories to show cause why a fraud order should not be issued against it. Toward the end of February, 1927, Cassel submitted an affidavit to the Post Office Department, declaring that he was authorized and empowered to execute it on behalf of the Cass Laboratories, and swearing:

> "That the business heretofore conducted under the name Cass Laboratories has been discontinued and abandoned and will not be resumed at any time in the future."

The facts were, that for a month or more before Cassel made this sworn statement, the name "Cass Laboratories" had been abandoned and the rheumatic public was receiving the same line of quackery sent out under a new trade name: "H. L. Cass Corporation."

It is to be hoped that when the Post Office Department gets around to these quacks again that it will appraise the oath of this concern at its obvious value and issue a fraud order not only against the company itself, but against the individuals who are conducting it.

Correspondence

INJECTION TREATMENT OF VARICOSE VEINS

To the Editor:—I was much interested in the editorial (The Journal, May 14, p. 1571), on "The Injection Treatment of Varicose Veins," which reported Lomholt's fatal case of pulmonary embolism. I have successfully treated more than a hundred patients by the injection method in the last five years, and have always assumed that embolism was a mechanical impossibility in these cases on account of the extreme toughness and firm adherence of the chemically induced thrombi.

The extreme degree and persistence of the acute inflammatory reaction in the injected veins in Lomholt's case suggests that the thrombi had become infected by pyogenic bacteria in the blood stream, perhaps from abscessed teeth or other foci. I have always insisted on the eradication of all foci of infection before injecting any varicose veins, and my occasional neglect of this precaution has usually been followed by a severe inflammatory reaction. Possibly, Lomholt followed the recent pernicious advice of Linser of Tübingen, who stated that the 20 per cent sodium chloride solution need not be boiled, "as it is self-sterilizing." I tried this once, got an infected thrombus, and have boiled my solution ever since. Finally, it is obvious from the data given that Lomholt's patient had a chronic myocarditis and developed auricular fibrillation. As pulmonary embolism is a fairly common complication of auricular fibrillation, and an excessively rare complication (according to the literature) of the injection treatment of varicose veins, it seems at least plausible to me that the embolus in this case came from the right auricular appendage rather than from the obliterated and firmly contracted long saphenous vein. It is unfortunate that there was no autopsy to settle this point. In any case, this experience of Lomholt is no argument against an excellent therapeutic procedure, as embolism has been reported several times following varicotomy, the embolus coming from the ligated proximal stump of the long saphenous vein.

Hermann Schussler, Jr., M.D., San Francisco.

A PIONEER PRECEPTOR

To the Editor:—In his paper on surgical progress, Kanavel mentions Parkes as the preceptor of Albert J. Ochsner. Dr. Ochsner had another preceptor who influenced him to take one of the most important steps of his career. When he was a young man teaching school at Ironton, Wis., saving a few hundred dollars that he might proceed directly to medical college, he was blessed with the friendship of E. J. Lewis, the village doctor. Dr. Lewis instructed the young man in anatomy and physiology and prevailed on him to enter the state university, where, in due time, he received the bachelor's degree in science. Dr. Lewis, himself a man of culture and descended through generations of a Connecticut family with root stock in Wales, was one of the men who thus early knew that success in medical work would increasingly require a higher degree of preliminary education. Without his influence, the work of Ochsner could not have been so fruitful.

Dr. Lewis, who was the father of the novelist Sinclair Lewis, removed to Sauk Center, Minn., where he continued practice to the time of his death last August. His friendship with Ochsner was continuous.

His home in Sauk Center was a center of culture, where many young physicians received helpful hospitality. He was one of the unostentatious lights, who point the way, where well known lights shine not.

S. H. Corrigan, M.D., Lampman, Sask.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ECZEMA OF HANDS AND FEET

To the Editor.—I have a patient suffering with a moist eczematoid condition of the skin of the hands and feet. This occurs annually about this time of the year and the warmer months of summer. It is exceedingly moist, saturating his stockings in a very short time. It progresses peripherally and has dry scaly margins. He has been to several dermatologists without any immediate relief and then takes up home treatment with petrolatum or epsom salt solution, which seem to [illegible]. I have had scrapings examined and have obtained a heavy growth of yeast. No other organisms have been found so far after two weeks' culture. The textbooks do not seem to offer any treatment. Can you suggest a course of treatment I might try? Please omit my name.

M.D., Philadelphia.

Answer.—Many of these cases of eczema of the hands and feet are ringworm infection. A very few are due to yeast. The ringworm (tineal) eczemas of the hands and feet are the commonest affections of these parts that the dermatologist sees. The condition is described in the works on dermatology under ringworm of the hands and feet, eczematoid ringworm, epidermophytosis, tineal dermatitis. It is only within recent years, however, that the very common role of tineas in causing eczema of these parts has been recognized.

In the acute cases wet dressings of aluminum acetate solution of the following formula is one of the best applications:

8 per cent aluminum acetate solution	30 cc.
Water	to make 500 cc.

Use this as much as possible, and, in the intervals when this cannot be used, keep the parts greased with a bland ointment such as cold cream. When the condition is subacute, antiseptics are indicated. Tincture of iodine from a strength of 2 per cent up to full strength (10 per cent) is one of the best applications. Various special mercurial antiseptic solutions are useful. One of the favorite applications is Whitfield's ointment:

Salicylic acid	6 per cent
Benzoic acid	12 per cent
Petrolatum	sufficient to make 100 per cent

This must be diluted to one third or one half strength in using at the start.

The foregoing suggestions indicate the line of treatment. More detailed treatment can be found in any of the recent works on dermatology.

THICKENED NAIL

To the Editor.—I have a patient who has a thickened and painful toe nail. The nail is too hard and thick to be cut off. Can you suggest anything that can be put on that will destroy the nail?

P. Stappenbeck, M.D., Brock, Neb.

Answer.—The best treatment would be the removal of the entire nail and the destruction of the matrix. Chemical destruction is a dangerous procedure.

TREATMENT OF AURICULAR FIBRILLATION

To the Editor.—What is the prognosis as to life and work of a patient who has had auricular fibrillation for five years but who has obtained normal cardiac rhythm under quinidine sulphate? Would it be advisable for him to have sexual intercourse or attend moving picture shows, ball games and the like? How long should he be kept on this medication? Please omit name.

M.D., N. Y.

Answer.—An opinion as to prognosis cannot be based on the presence or absence of auricular fibrillation. The prognosis depends:

1. Above all other considerations, on the presence or absence of an active infection involving the heart itself. This might be an endocarditis so mild as to give slight symptoms but constantly doing progressive harm.

2. If such infection is not present, on the recurrence with consequent further harm. A heart previously infected is predisposed to such infection.

3. On the amount of anatomic change already present and whether it is sufficient to impair the function of the heart, and if it is, to what extent the function is impaired.

4. To a relatively small extent on occupation and mode of life.

The presence or absence of auricular fibrillation is little of a determining factor in the prognosis except that the presence of auricular fibrillation usually indicates some amount of injury to the heart. Auricular fibrillation is not a great mechanical disadvantage, provided the rate is not too rapid or that it is controlled by digitalis. A patient with an otherwise competent heart, when anatomic changes in the valves or muscles have not progressed too far and with no active infection present, can go through life comfortably and indefinitely with an auricular fibrillation.

The question as to the mode of life and amount of exercise depends so closely on the factors mentioned that the decision in this particular case must be left to the judgment of the correspondent. In general, severe exertion would tend to cause auricular fibrillation to recur and his activities should be increased gradually if it is thought best to increase them. If he has gone five years without recurrence, the quinidine could certainly be stopped, and in the absence of any evidence of infection his activity could be gradually increased, the amount of increase depending on his response.

RECURRENT SWELLING OF SPERMATIC CORD

To the Editor.—I have a patient in whom swelling of the spermatic cord from the testes up as far as it can be felt, and presumably the seminal vesicles, occurs gradually for about seven days after sexual intercourse. Just after intercourse the swelling entirely disappears along with the pain, which is, no doubt, due to the tension. At the seventh day the swelling is quite prominent on both sides. There is no varicocele. The patient had an operation on the left side two years ago for hernia, but the swelling has been taking place for four years. He had syphilis about twenty years ago; subsequent Wassermann reactions, the last one two years ago, were negative. He never had gonorrhea. There is a mild prostatitis with pus cells but without organisms. I have been giving diathermy, massages and irrigations. Kindly advise probable cause and treatment. Please omit my name.

M.D., Louisiana.

Answer.—The recurrent swelling of the cord is undoubtedly due to a chronic inflammation of the seminal vesicles and subsequent atony of these organs. Stripping of the vesicles, if done only with the finger, does not furnish results; it has to be executed by a massage instrument devised for this purpose. Occasionally vasostomy and subsequent injections of an antiseptic solution give results. The same is true of intravenous injection of small doses of neoarsphenamine. If all this fails, relief of the periodic swelling of the cord is brought about by resection of the tunica of the vas.

NERVOUS SYMPTOMS AFTER THYROIDECTOMY

To the Editor.—A woman, aged 39, was taken to the hospital with symptoms of toxic goiter. The rate of metabolism was + 85. On treatment with compound solution of iodine this went down to + 35, when thyroidectomy was performed. One fifth of the gland was left in. After the operation the patient felt fairly well. About eight days later she commenced to get attacks of nervousness and tremor, especially in the mornings. Again compound solution of iodine was given to her for a few days but without result. Therefore, this medicine was changed to parathyroid extract combined with calcium lactate, given orally. The patient apparently responded well to this medication, being able to get out of bed and walk around in the house, and the tremor seeming to ameliorate. A few days ago, that is, six weeks after the operation, however, the patient began to have severe attacks of sleeplessness, palpitation, tremor with tendency to jump out of bed, and pains in the heart region which made lying on the left side impossible. Now I started to give her calcium chloride intravenously with simultaneous oral administration of parathyroid extract, but it is too early yet to draw any conclusion regarding the result. I would appreciate any suggestion concerning treatment. Kindly omit my name.

M.D., New Jersey.

Answer.—The condition described may be due to a persistent hyperthyroidism because of the amount of thyroid tissue that was not removed at operation. It is therefore suggested that another basal metabolic rate be obtained. At any rate, it is advisable at this time not to give more compound solution of iodine. If the basal metabolic rate is still elevated, prolonged rest with sedatives and an attempt to remove any focus of infection should be instituted. If after a fair trial this is of no avail, it may be necessary to remove that portion of the thyroid gland still remaining. There is a possibility that the symptoms described may be due to removal of parathyroid tissue at operation. It is necessary to know whether the patient's myotatic irritability is increased, whether a Chvostek sign is present, and whether the threshold of the electrical excitability of the peripheral nerves is decreased. If these are positive, treatment should be continued.

Minnesota January Examination

Dr. A. E. Comstock, secretary of the Minnesota Board of Medical Examiners, reports the written, oral and practical examination held at Minneapolis, Jan. 4-6, 1927. The examination covered 15 subjects and included 80 questions. An average of 75 per cent was required to pass. Forty-five candidates were examined, all of whom passed. Twenty-two candidates were licensed by reciprocity. The following colleges were represented:

OWNERSHIP OF ROENTGENOGRAMS AND HOSPITAL RECORDS

Careful search has failed to reveal any case in which a court has decided whether a person who is roentgenographed is, in the absence of an express agreement, entitled to the resulting roentgenogram. A somewhat similar question has been decided, however, with respect to the right of a person photographed to the photographic negatives incident to the process. Courts have held that the negative is the property of the photographer, subject to certain restrictions on its use.[1] But the parallel is not perfect; every one knows that a person who presents himself to a photographer to be photographed expects to receive a photograph and does not expect to receive any intermediate product of the process of manufacture, but it is not clear whether a person who presents himself to be roentgenographed expects to receive, and the roentgenologist expects to give, an opinion and advice, or a roentgenogram, or both. In the absence of an express agreement, a court that is called on to determine the question will try to find out what was in the minds of the parties to the transaction at the time it occurred. To that end it must look for proof of a reasonably definite and generally recognized understanding among roentgenologists and their patrons with respect to the matter.

Proof of any understanding whatever among the nonprofessional public would probably be difficult. Persons of this class are referred to roentgenologists, present themselves for examination, and await the reports of the results, which they receive through their physicians; they do not stop, before being roentgenographed, to ask whether or not they are going to receive roentgenograms. Among roentgenologists and physicians generally, however, a common understanding is more readily susceptible of proof. A formal statement of that understanding by a representative professional group is to be found in resolutions adopted in 1920 by the Radiological Society of North America. There it is expressed as the sense of the society that all roentgenograms, plates, films, negatives, photographs, tracings or other records of examination are the exclusive property of the roentgenologist who made them or of the laboratory where they were made. The roentgenologist is declared to be a professional man, whose opinion and advice are sought; he is not a mere technician, paid to make a certain kind of photograph called a roentgenogram. He is a consultant in all cases in which he is called on to examine patients; therefore he is not to make known to a patient or to a patient's relatives, friends or guardian any of his observations or conclusions. He is not to deliver to any of them any plate, negative, film or print unless requested so to do by the physician who referred the patient for examination or who is in charge of the case. Evidence showing a general acceptance by the profession of the principles laid down in these resolutions will go a long way, in the absence of an express agreement, toward settling the question of the ownership of the roentgenogram, if and when that question comes before the courts.

The fact that a roentgenogram was made by a hospital, through its roentgenologist, and not by a roentgenologist acting for himself, does not alter the situation just stated, except that it makes a stronger case for the retention of the roentgenogram by the hospital. A hospital may make such reasonable regulations as are necessary for its efficient management. If any such regulation is in fact brought to the attention of a patient or a physician using the hospital, or if he has actual knowledge of that regulation, before he enters on such use, he is bound by it. The fact that the regulation is posted in and about the hospital or even that it has been customarily followed for a long time would tend to prove such knowledge on the part of a physician or a patient and to bind him accordingly. If any such regulation requires that the records, including roentgenograms, remain in the hospital, it would presumably be sufficient to compel a physician or a patient to leave his case records there, including roentgenograms.

---

[1] Corliss et al. v. Walker Co. et al., 64 Fed. 280. Pollard v. Photographic Company, 49 Ch. Div. 345.

Whether a patient may as a matter of right inspect his hospital records, including any roentgenogram that may form a part of it, or may have that record inspected on his behalf, or may make a copy of it or have a copy made, and whether he may require the hospital to provide him with a copy of the record on tendering the cost of making it, are questions that the courts have apparently not been called on to decide. If such questions are fairly presented, a court may not unreasonably hold that a patient is entitled to make such an inspection or to have it made, under conditions that do not interfere with the orderly operation of the hospital It seems not unlikely, too, that the court may hold that a patient is entitled to a copy of this hospital record so far as it is necessary to his welfare, at least on payment of the cost of preparing the copy. The fact that these various questions have never been carried to the courts of last resort and possibly to no other courts suggests very strongly that they are usually settled by the parties on the basis of equity and common sense—which, after all, is the very best way to settle them.

Book Notices

Studies in Intracranial Physiology and Surgery. The Third Circulation. The Hypophysis. The Gliomas. By Harvey Cushing, M.D. The Cameron Prize Lectures delivered at the University of Edinburgh, October 19, 20, 22, 1925. Cloth. Price, $3.25. Pp. 146, with 16 illustrations. New York: Oxford University Press, 1926.

The three Cameron prize lectures given by Cushing at the University of Edinburgh have been published in book form. They represent the work of his pupils and himself on the cerebrospinal fluid, the hypophysis and intracranial tumors. One marvels at the amount and diversity of the investigations which he has pursued, but his greatest contribution is perhaps the enthusiasm and spirit for research which he has stimulated in others. Herein he is kin to the great teacher whose life he has told so vividly. The lectures not only tell the story to date but are full of unsolved queries which will probably direct the lines of future work on these subjects.

Handbuch der inneren Sekretion. Eine umfassende Darstellung der Anatomie, Physiologie und Pathologie der endokrinen Drüsen. Herausgegeben von Dr. Max Hirsch. Band I. Lieferung 2. Band II. Lieferung 2. Paper. Price, 13.50 and 12 marks. Pp. 197-336, and 277-422, with illustrations. Leipsic: Curt Kabitzsch, 1927.

These two divisions of this ambitious system contain chapters on the hypophysis and epiphysis by Aschner, chapters on the mammary glands, uterus, vagina and placenta by Lahm, a chapter on the testis by Jaffe and Berberich, and a chapter on the epididymis and the prostate by Fischer. Both numbers are well illustrated with anatomic preparations and photographs. Dr. Aschner is one of the earlier workers in the field of hypophysial physiology by the method of extirpation. The informed reader finishes Dr. Aschner's chapter on the hypophysis with the feeling that the Viennese investigator is not down to date. For example, in such an ambitious undertaking published in 1927 one certainly would expect reference to the important work of Smith, Evans, Borquin and others in this country on the various phases of hypophysial physiology, as well as reference to the experiments of Dandy and of Horrax on the pineal body. One looks in vain for either. The clitoris is listed as an organ of internal secretion, but fortunately Dr. Lahm sums up the discussion on this subject with the statement that "nothing is known concerning the internal secretion of the clitoris." The same author concludes in the chapter on the placenta that "it is yet an open question whether the lipoids of the placenta are specific" and that "nothing definite has been proven regarding the hormone character of the placenta lipoids." The final statement on the placenta as an endocrine organ reads, "According to the best information to date the placenta is not an independent organ of internal secretion."

Tuberculosis: Bacteriology, Pathology and Laboratory Diagnosis with Sections on Immunology, Epidemiology, Prophylaxis and Experimental Therapy. By Edward R. Baldwin, M.D., Director of the Trudeau Foundation, S. A. Petroff, Ph.D., Bacteriologist and Director of Trudeau Sanatorium Research and Clinical Laboratory, and Leroy U. Gardner, M.D., Pathologist and Director of Saranac Laboratory for the Study of Tuberculosis. The Trudeau Foundation Studies. Cloth. Price, $4.50. Pp. 342, with 86 illustrations. Philadelphia: Lea & Febiger, 1927.

In this book the fields indicated within the broad scope of the title are covered with extraordinary conciseness without sacrifice of important, informing detail. The work represents an excellent selection of the significant. After a brief historical introduction, the subject matter is opened with chapters on the tubercle bacillus, which are properly conventional but at the same time cover recently established contributions to the subject. Chapters on experimental tuberculous infection, reinfection and immunity bring together in a well written section material heretofore widely scattered in the literature of tuberculosis, much of it coming originally from or directly inspired by the laboratories from which this book emanates. Two chapters on the pathologic anatomy of human tuberculosis would be a credit to any textbook of general and special pathology, and have the special merit of making available for general reading some of the authors' own studies, such as the anatomic healing of intestinal tuberculosis. There is a clear and also optimistic chapter on epidemiology, in which the factors responsible for the recent rapid decline in tuberculosis mortality are outlined and analyzed. The section on laboratory methods in diagnosis fills a long felt want in public health, research and hospital laboratories. Careful captioning and subheading of the subject matter make of the work an extensive outline as well as an adequate treatise. Investigators in any of the fields touched will find the bibliography cited well selected. In spite of the extent of scientific material covered by the book, the authors have found space in its 300 pages to furnish brief, practical instructions on the minor but neglected matter of the care of animals. The press work is excellent and the illustrations are clear.

Exophthalmic Goitre. By John Eason, M.D., F.R.C.P.E., Physician, Royal Infirmary, Edinburgh. Cloth. Price, 12/6 net. Pp. 215, with illustrations. Edinburgh: Oliver & Boyd, 1927.

The author should be congratulated on bringing before the profession in concise form the essentials of the subject. The book is not intended to be an encyclopedia but a monograph correlating the latest views and presenting in a condensed manner the author's conclusions and how and why they were formed. The exposition is rapid and clear, with many graphic references to recent literature. Its excellence of literary style, its systematic organization and its presentation of precise practical deductions call for special appreciation. The subject is treated in a critical rather than a dogmatic manner. Although brief the text is full, and clearness has not been sacrificed for brevity. The author has been successful in his endeavor to appraise "the relative importance of the sympathetic and parasympathetic divisions in regard to symptomatology and pathogenesis and to show the relationship of autonomic tone to general nervous excitability, general cell hyperactivity and thyroid hyperfunction." The first chapter deals with the difficult subject of the general anatomic and physiologic considerations of the thyroid vesicle as the unit of secretion. In succeeding chapters, the etiology, symptomatology, pathologic changes, prognosis and treatment are clearly dealt with. The indications and contraindications for the different forms of treatment, medical, roentgen-ray and surgical, are definitely and clearly set forth. The author does not deal with the technic of operation or with psychotherapy, but other forms of treatment are discussed in a thorough manner. The author is skeptical with regard to the reliability of conclusions founded only on animal experimentation The book is in every sense of the word practical, replete with suggestions, and valuable not only to the specialist but also to the general practitioner who desires a clear, full sketch of the present knowledge of exophthalmic goiter without having to read all the voluminous and often conflicting literature on the subject

THE NATURAL HISTORY OF OUR CONDUCT By William E Ritter, President of Science Service With the Collaboration of Edna Watson Bailey, Lecturer in Education & Association Director of Practice Teaching, University of California Cloth Price, $3 50 Pp 339 New York, Harcourt, Brace & Company, 1927.

The evolutionists are, of course, convinced that not only *the body of man but also his behavior is a direct development* from lower forms The purpose of Dr Ritter's volume is to establish not only the former fact but also the latter He indicates that the only successful animal activities are those which are purposeful, but there are also maladaptive activities which work for the destruction of the animal Human beings also act occasionally for their own destruction One of the remarkable facts is the lack of regret, sorrow, remorse or sympathy in animal forms in active destruction to their own kind However, Dr Ritter expresses the belief that many mammals and birds do possess the germs of moral *consciousness He traces adaptive activities of* self-injury through the birds, the mammals and the anthropoid apes to a similar process among human beings of low culture and of high culture Unfortunately, some of the problems concerned have been so little studied that conclusions are difficult Man is the most adaptive of all living beings, that adaptation has come about through his gradual development over a vast period of time

KURZES LEHRBUCH DER CHEMISCHEN PHYSIOLOGIE Von Dr Ernst Schmitz, o o Professor an der Universitat Breslau Second edition Cloth Price, 16 80 marks Pp 384 Berlin S Karger, 1927

This short textbook covers the ground usually included in the older works on physiologic chemistry It is a good introductory volume The first two chapters are devoted to general remarks together with brief but hardly worth-while discussions on solutions, osmotic pressure, electrolytic dissociation, colloids, surface tension, and mineral composition of organisms Then follow brief but good descriptive chapters on lipins, carbohydrates, proteins and nucleoproteins Many new observations are cited, but little attempt is made to try to organize the material for the student on a general fundamental organic chemistry basis The enzymes are treated briefly under digestion Absorption is well treated from the standpoint of specificity, but there is no theoretical discussion on the possible mechanisms involved Blood and lymph are discussed at *some length, but the student is not aided in* finding his way through the maze of terminology which has crept into the literature on the subject of blood coagulation Then follow chapters on the liver, muscle, nerve, connective tissue, milk, urine, skin, internal secretions, respiration and general metabolism Muscle metabolism and the chemistry involved in muscle activity are well treated The book is well bound and excellently printed

EXAMINATION OF CHILDREN BY CLINICAL AND LABORATORY METHODS By Abraham Levinson, B S , M D , Associate in Pediatrics, Northwestern University Medical School Second edition Cloth Price, $3 50 Pp 192, with 85 illustrations *St Louis C V* Mosby Company, 1927

Those physicians who argue that the child is merely a small replica of the adult, and that it is only necessary to consider his physical disturbances in that light, will find much cause for revising their opinion in this practical guidebook to methods of physical examination as applied to the child All the subjective symptoms and the history to which one gives such care *in examining* the adult are here had at second hand from the mother or some other relative The technical procedures in which the adult frequently cooperates are carried out on the child sometimes under conditions of great resistance The conditions of the *blood* both as to morphology and as to chemistry vary greatly All apparatus applied directly to the infant is obviously in miniature. These are the considerations underlying Dr Levinson's contribution The advice given is direct All the chapters are fully illustrated, and the methods are based on extensive experience both in the hospital and in the home Of greatest importance are the indications under which certain diagnostic procedures are warranted These the author selects with a practical conservatism

KLINISCHE SYMPTOMATOLOGIE UND DIFFERENTIAL DIAGNOSE INNERER KRANKHEITEN Band III Weitere klinische Symptome und Differential Diagnose Von Prof Dr Norbert Ortner, Vorstand der II med Klinik der Universitat Wien, Hofrat Second edition Paper Price, 21 marks Pp 457 Berlin Urban & Schwarzenberg, 1927

It is difficult to review this work because of its encyclopedic character The contents are so extensive that the best that can be expected is a short description of any one subject The author *has succeeded, nevertheless, in giving in* presentable form a differential diagnosis of all the tumors of the abdomen and all the conditions associated with fever, pulmonary and cardiac diseases, liver enlargements and the psychasthenic states The value is enhanced by a marginal index whereby the subject matter sought for can be easily located A differential diagnosis of conditions associated with fever is so vast that one can hardly expect much in twenty-eight or thirty pages It would seem, therefore, that this discussion were better eliminated and more space devoted to other conditions There are too many repetitions in the section devoted *to abdominal tumors This is due to the* overlapping of tumors from one part to another of the sections in which the abdomen is divided for discussion On the whole, the book is satisfactory for physicians who want a rapid aid in diagnosis

Books Received

Books received are acknowledged in this column, and such acknowledgment *must be regarded as a sufficient return for the courtesy of the* sender Selections will be made for more extensive review in the interests of our readers and as space permits Books listed in this department are not available for lending Any information concerning them will be supplied on request

CHIRURGISCHE RONTGENOLOGIE Ein Grundriss der Anwendung der Rontgenstrahlen in der Chirurgie mit einem Anhang Radiumtherapie Von Dr Hans Kurtzahn, Privatdozent fur Chirurgie (chirurgische Universitats Klinik, Konigsberg) Mit einem Geleitwort von Prof Dr M Kirschner Direktor der chirurgischen Universitats Klinik, Konigsberg Paper Price, 10 20 marks Pp 216, with 110 illustrations Berlin Urban & Schwarzenberg, 1927

Brief text with outline of technic and indications

EXPERIMENTELLE UND KLINISCHE BETRACHTUNGEN UBER DIE GLEICHFORMIGKEIT VON NERVEN , HORMON GIFT UND IONENWIRKUNG AUF DIE WASSERBEWEGUNG IM ORGANISMUS Von Fr Kraus Heft 2 Sammlung der von Nothnagel Stiftung veranstalteten Vortrage Paper Price, 1 80 marks Pp 23, with 4 illustrations Berlin Urban & Schwarzenberg, 1927

Showing that the water metabolism of the body is a complicated process

HISTORY OF CARDIOLOGY By Louis Faugeres Bishop, M A, M D , Sc D , President, Medical Association of Greater City of New York, and John Neilson, Jr , B S , M D , Assistant in the Cardiac Clinic, St Luke's Hospital, New York With an Introduction by Victor Robinson, Ph C , M D Cloth Price, $5 Pp 71 New York Medical Life Press, 1927

A tracing of scientific attempts to solve the problems of heart disease, but with a large price for such a small book

THE HARVEY LECTURES Delivered Under the Auspices of the Harvey Society of New York, 1925 1926 Under the Patronage of the New York Academy of Medicine Series XXI By Dr F R Nager, Dr John H Northrop, Dr Warren H Lewis, Dr Edwin B *Wilson, Dr* Knud Faber, Dr B Brouwer and Dr J B Collip Cloth Price, $4 Pp 229, with illustrations Baltimore Williams & Wilkins Company, 1927

Classic lectures on a variety of medical topics

ANTIGENOTHERAPIE DE LA TUBERCULOSE PAR LES EXTRAITS METHYLIQUES DE BACILLES DE KOCH Par L Negre, et A Boquet, Chefs de laboratoire a l'Institut Pasteur Preface du Professeur A Calmette, membre de l'Academie de medecine, sous-directeur de l'Institut Pasteur. Paper Price, 16 francs *Pp* 158, with illustrations Paris Masson & Cie, 1927

Clinical report on use of tuberculins

Typhoid Not Accidental Compensable Injury

(Buchanan et al v Maryland Casualty Co (Texas), 238 S W R 116)

The Commission of Appeals of Texas, section B, says that this cause was before the supreme court on a certificate from the court of civil appeals presenting for determination three questions Under the workmen's compensation act (of Texas), is typhoid, contracted by an employee as a result of impure water or food furnished by an employer, an accidental injury under the terms of the act? Under the workmen's compensation act, is typhoid, contracted by an employee as a result of the impure water or food furnished by an employer, a compensable injury? Was the trial court correct in sustaining a general demurrer to the claimants' petition, or was it error for the court of civil appeals to affirm the holding of the trial court in that respect? In this case an employee of a development company while working in its oil fields was stricken with typhoid, from which he died The claimants of compensation for his death averred that he contracted the fever by reason of the food or drinking water furnished him by the company But the commission of appeals was not able to find any decision allowing recovery in this kind of a case under a statute similar to that of Texas Under statutes similar to that of Texas it is the uniform holding of the courts that before any disease is compensable it must be the direct result of an injury Not only so, but that injury must be to the physical structure of the body This language has been construed to mean that the disease must result from violence on *the external portion of the body* The decision of the court of civil appeals in this case is in line with the authorities in other states which have statutes most similar to that of Texas, and it is recommended that the first question certified be answered in the negative, that the second question be answered in the negative, and that the third question be answered to the effect that the trial court correctly sustained the general demurrer and that the court of civil appeals reached the right conclusion in affirming such action by the trial court The opinion of the commission of appeals answering certified questions adopted and ordered certified to the court of civil appeals

"Good Health," "Illness," "Disease," "Sickness"

(Northwestern Mut Life Ins Co v Wiggins (U. S), 15 Fed R (2d) 616)

The United States Circuit Court of Appeals, ninth circuit, in affirming a judgment of dismissal, says that the plaintiff insurance company by suit in equity sought to cancel a policy issued by it, March 19, 1924, on the life of one Wiggins, on the ground that material false statements were knowingly made by him as to the condition of his health The plaintiff asserted that the insured had for several years had myelogenous leukemia, which caused his death, Sept 4, 1924 The trial court found that about four years prior to his application for the insurance he had some teeth extracted and bled profusely, that his family physician found that he had the disease referred to treated him for some time, and in July, 1922, advised him to take treatments from a roentgenologist, who gave him treatments into February, 1924, during which time he reported to his physician as often as once every two weeks to have an examination of his blood Neither physician ever disclosed to him the nature or character of his trouble, but made every effort to keep such knowledge from him They frequently, however, discussed with him his blood count, and his family physician once told him that he had anemia, and probably used the word "chronic" In his application for insurance he stated that he last consulted a physician 'two weeks ago, for general examination,' and answered 'Yes" to the question, "Have you fully recovered and are you now in good health?" He also answered "No' to questions asking him whether he had had any illness, disease or accident during the past ten years not mentioned, and whether he had had since childhood any chronic or constitutional disease or severe injury not fully set forth

Did the insured have knowledge of serious impairment of health? He knew he had 'chronic" anemia, that is, it had continued for some time. "Good health," "illness" and "disease" must be considered, in an application for insurance, not in the light of scientific technical definitions but in the light of the insured's understanding in connection with which the terms are employed in the examination. The most specific information that he had was that he had an impoverishment of the blood, or "thinness of the blood." This condition, the record disclosed, may be occasioned by hemorrhage. In the insured's case the inception of the condition to his mind was the extraction of teeth, which was no accident, and the physicians studiously kept from him his true condition. His condition did not interfere with his usual avocation. No indisposition of health had interrupted his daily attention to business except a day or two for a cold. He did not complain to his family or to any one with whom he came in contact. His family believed that he was in good health. "Sickness" is a condition interfering with the usual avocations. He took on new responsibilities by increasing his interest in business many thousand dollars. He was active and energetic. He was a layman, and, while he may have been conscious of a weakened condition of the body, perhaps from the loss of blood from the cavities of the extracted teeth, the proof did not establish such fact or that he knew he had a disease which tended to weaken or to undermine his constitution. He looked well; the examining physician believed that he was a good risk. His ignorance of affliction by disease or impairment of health was emphasized by the fact that he did not make his will until a month before his death. His answers were not warranties, and were presumed to be true. Fraud is never presumed, and to cancel the policy the burden was on the complainant to show that the answers were false by clear, cogent, convincing and certain proof. This court believes with the trial court that the plaintiff did not sustain the burden imposed by law.

Liability for Suicide of Patient in Sanatorium

(Smith v. Simpson et al. (Mo.), 288 S. W. R. 69)

The Kansas City (Mo.) Court of Appeals, in affirming a judgment for $3,000 for the plaintiff, for the death of his wife alleged to have been caused by the negligence of the defendants and their servants, says that the defendants were physicians who, as copartners, owned and conducted a private sanatorium in which Mrs. Smith was a patient and committed suicide by hanging herself from an elbow of a steam pipe, by the use of sheets. There was testimony in the plaintiff's behalf which tended to show that his wife was afflicted with nervous and mental disease with suicidal mania, and manifested a disposition to destroy herself, and that the defendants were fully informed of her condition when they accepted her as a patient after examination. As the court read the petition, the crux of the negligence charge was that the defendants failed to use ordinary care to watch Mrs. Smith, and thereby prevent her self-destruction, by reason of her alleged nervous and mental derangement. There was substantial evidence that the defendants knew of her suicidal tendency. There can be no question that it is the law that the defendants were required, not only to use ordinary care in treating the patient for her illness, but also to safeguard her from injuring herself by reason of her suicidal tendency.

It seemed to be the defendants' contention that, before the plaintiff could recover damages, he was required to prove that his wife was insane, but the court thinks that this contention was without merit in view of the fact that the allegations of the petition did not include insanity. It was not disputed that all the authorities hold that private hospitals owe to their patients such ordinary care and attention as the mental and physical condition of such patients reasonably requires. The law demands reasonable care, such care as a reasonable man would take under the circumstances existing; but no man is required to take measures against a danger which the circumstances as known to him do not suggest as likely to happen. These circumstances include the patient's mental condition and aberrations, and what he is likely to do by reason thereof, and the dangers afforded by his surroundings.

The plaintiff having produced substantial evidence in support of the allegations of his petition, this court must hold that there was no error in the action of the trial court in overruling the defendants' demurrer at the close of the evidence of the plaintiff. At best, there was raised an issue of fact for the jury's consideration. To the contention that an instruction to the jury was erroneous because it allowed recovery unless the defendants had nurses stationed to watch Mrs. Smith day and night, which was contrary to the care and duty imposed on them, the court answers that, as already stated, the degree of care and diligence required of the defendants was to be measured by the mental and nervous condition of the patient and the indicated dangers surrounding her.

There can be no question about the liability of a privately owned hospital or sanatorium, conducted for individual gain and not for charitable purposes, for damage to its patients resulting from negligence attributable to the owners or agents of such hospitals. Moreover, in the face of the record, the court is unwilling to accept as conclusive the defendants' argument that, if the plaintiff established the fact that his wife was insane and that she was suffering from suicidal mania, then he also established, under the proof offered, that she would never get well, and therefore that he had not been damaged. It must be held that the husband was entitled to compensation for the loss of the society and comfort of his wife as against any one negligently depriving him thereof. The question as to the amount of his damage was for the jury to determine, under all the facts and circumstances in evidence.

Examination and Testimony with Regard to Sanity

(Blocker v. State (Fla.), 110 So. R. 547)

The Supreme Court of Florida, in affirming a conviction of defendant Blocker of murder in the second degree, says that he relied on the defense of insanity. When a physician, who qualified as an expert and testified that he had examined the defendant in 1923 and again on the day before he gave testimony, was asked as to what condition he found the defendant in regarding mentality, objection was made that that was irrelevant; also that when the defendant was examined in 1923 his counsel was not present, because not invited to be present, and that in the absence of his counsel there was a deprivation of the defendant's constitutional rights. But evidence tending to show the insanity of the defendant in a criminal case makes material and relevant evidence tending to establish his sanity, when offered by the state in rebuttal. Furthermore, it is not necessary to the admission of evidence about the examination of a defendant in a criminal case, for the purpose of ascertaining his sanity or insanity, to show the presence of his counsel or notice to him. Such an examination ought not to be surreptitious or clandestine, but must be fairly and impartially made. However, there is no rule of law requiring the presence of, or an invitation to, the defendant's attorney to be present on such an occasion. An examination of a defendant to ascertain his mental condition is not a deprivation of his constitutional rights, nor does such an examination require him to give evidence against himself. It was apparent that the defendant in this case had full opportunity to cross-examine the alienists, and he did so. There was nothing to indicate anything but a painstaking examination of the defendant by the alienists, and, from this examination, under the law, it was the privilege of the parties to have such experts express their opinions as to the sanity of the defendant, and this without first detailing the circumstances or the course of such examination. The opinion of an expert witness as to the sanity of a person may, under the law, be given, subject to such cross-examination as is proper. An expert on insanity may give an opinion based on his own examination of a person, on his observation of that person, or on any state of facts, supported by some evidence in the case, which he assumes as true; but the judge should be informed whether he bases his opinion on his own knowledge, or on a hypothetic state of facts, and should know what portion of the evidence he has assumed to be true in forming his opinion. It is not required that a court caution a jury as to the value of expert testimony, or of the opinion of an expert on insanity given in answer to a hypothetic question. But the jury is entitled to all the facts on which the expert bases his opinion. If he answers a hypothetic question, the facts therein set forth must have been proved on the trial. If he rests his answer on facts and knowledge he has acquired himself, he must impart them to the jury, if asked to do so.

Ann Arbor, Mich, in the Chair

Officers for 1927-1928

The officers of the association are president, A S Warthin, Ann Arbor Mich vice president, C P Howard, Montreal, secretary J H Means, Boston, recorder, Thomas R Boggs, Baltimore treasurer, George Blumer, New Haven, Conn; councilor, Joseph A Capps, Chicago

Hypertrophy and Dilatation of the Heart

Dr J A E Eyster, Madison Wis The theory of increased activity of the muscle is universally accepted the alteration in dynamics being the basis for this idea Alteration in the nutrition of the muscle may also play a role, but the idea of stretching of the muscle has not had experimental support In our work we have made experiments on dilatation preceding hypertrophy In studying experimental aortic stenosis and aortic regurgitation, puncture of the ventricular septum has been followed by an increase in size which reaches its maximum in seven days and disappears by the tenth day, when the heart is even smaller than normal, secondarily there occurs a later phase of enlargement which reaches its maximum in 100 days The heart is then longer and wider In experiments on occlusion of the aorta and running salt solution into the heart under high pressure the results were similar There seem to be two stages to these phenomena, the first due to stretching of the muscle and the second stage a hypertrophy of the muscle In the lesions experimentally produced the apex is the weakest part of the structure The same factor seems to hold true clinically The histologic picture shows increase in the size of the cells Venous pressure is not increased at first We divided the two stages of the lesion—the period of stretching, and the period of hypertrophy—and made the test of removing the band round the aorta on the third day It was found that the lesion progressed in the same manner Our studies were checked up by roentgen-ray examination and by clinical methods in man We found a distinction between hypertrophied and normal hearts There was no evidence of hypertrophy unless there was organic disease Clinical hypertension can exist many years without developing hypertrophy Our conclusions are, therefore, that injury to the muscle is one of the factors necessary to produce hypertrophy Whether increased work is the cause must be tested by further experiment

Changes in Human Electrocardiogram Following Iodine Medication and Thyroidectomy

Dr W W Hamburger, Chicago Studies have been made on early hyperthyroidism with the previously undamaged heart, and also studies on the result of the use of iodine in these cases In one patient, a girl of 16, who reacted unfavorably to compound solution of iodine, the T-wave went up and there was some evidence of decompensation Under digitalis treatment there was a drop in the T wave, although the reaction was unfavorable to iodine In seeking the reason for these changes in the T-wave following thyroidectomy, we may consider, first, probable changes with the slowing of the pulse rate, and, secondly, changes in the structure of the heart muscle which occur with changes in the T-wave in connection with changes of electric potential Also there are changes in the nervous regulatory control of the heart We need further studies to show which change is most constantly present In studies on normal people with the administration of iodine the results were conflicting Some had change in the T-wave and some did not The basal metabolism was not changed Iodine caused diminution of the T-wave in 50 per cent of cases Thyroidectomy caused the greatest diminution of the T-wave There was frequently inversion of the T-wave following thyroidectomy.

Association of Severe Anemia and Angina Pectoris

Dr James B Herrick, Chicago I have encountered three cases of severe anemia with typical anginal attacks One was a case of pernicious anemia, one, a case of myocardial disease and a severe anemia like pernicious anemia, and the third, a case of severe anemia in which the hemoglobin was only 16 per cent, because of hematuria of a year's duration This man had very distinct anginal attacks increasing in severity There were marked cardiovascular changes and high blood pressure The man lived several months, and autopsy showed carcinoma of the right kidney The coronary artery was sclerosed and there was fatty infiltration of the heart The lesson to be drawn from this series is that some patients with angina might need treatment directed to the improvement of the blood condition An improvement in general hygiene, including change of climate and a diet rich in carbohydrates and vitamins, would be indicated

DISCUSSION

Dr F T Lord, Boston: I have had 140 cases of angina, and only one case with significant anemia attributable to chronic nephritis

Dr George Kober, Washington, D. C: My personal experience with angina pectoris convinces me that toxins are capable of developing these lesions, and when the source of the toxins is removed the *vis medicatrix naturae* is capable of removing the damage inflicted My teeth apparently were the offenders in my case

Dr H Z Giffin, Rochester, Minn · In our experience, the attacks have been much milder than anginal attacks of other types There was only one instance of severe angina in pernicious anemia The cases formed 3 per cent of the total number of pernicious anemia cases The electrocardiographic findings were not remarkable, but autopsy showed stenosis of the coronaries

Dr Lewis A Conner, New York· This paper supplies evidence in favor of a coronary origin in cases of this type I have seen two such instances A distinguished surgeon in New York had attacks of angina which grew progressively worse until they were intolerable Then he developed pernicious anemia The attacks coming on frequently made his nights terrible on account of their severity When his attacks became so bad, he was given a large transfusion As a result of a transfusion of 1 000 cc, the attacks stopped suddenly He never had another attack until his blood became so low as to require a second transfusion After three or four weeks, the pain was relieved He had about forty or fifty transfusions at intervals of three or four weeks When the blood reaches a certain level the anginal attacks return and are an indication for another transfusion

Dr Henry A Christian, Boston There are two anatomic factors in relation to this subject First, the heart muscle is increased in bulk in severe anemia, patients with pernicious anemia have hypertrophic hearts and there is more muscle demanding blood supply Second, this heart muscle shows a very characteristic degeneration

Dr L G Rowntree, Rochester, Minn. Was there any lowering of the blood pressure in these cases? I have seen a similar condition occurring in Addison's disease in which the blood is normal, but the circulation is very poor. The anginal symptoms are mild, however

Dr S A Levine, Boston I had a similar experience to that of Dr Conner My patient had typical angina pectoris, in bed, without effort. The blood count was very low. I did a transfusion. The patient had no more attacks of angina after one transfusion. I think that the combination of coronary arteries and angina pectoris is not common. I do not think it likely that the anemia itself is the cause of the angina. The anemia would not initiate the attack without some background of coronary disease.

Dr. James R. Herrick, Chicago: I think that some of these cases are purely accidental. Perhaps the best answer is that as the blood improved the anginal attacks improved. Anemia is not the primary cause. There must be cardiovascular factors underlying the condition. I did not take blood pressure readings in these cases, so I cannot say whether it was high or not.

Pathogenesis of Syphilitic Aortic Insufficiency

Dr. R. W. Scott, Cleveland: Syphilitic lesions are an important cause of heart failure when they involve the root of the aorta. Aortic insufficiency is related to infiltration of the aortic ring or to lesions distal to the cusps. Usually, the aortic leaflets are invaded near the commissure, which is the spot most frequently involved in syphilitic hearts. The earliest lesions show obliterative changes in the arterioles in the region of the commissure, and also proliferation of new blood vessels. Therefore, syphilis spreads through the commissure to the aortic leaflets, through widening of the commissure. A late result seen at necropsy is due to fusion of the aortic intima with the aortic leaflets.

Relation of Syphilis to Angina Pectoris

Dr. Harlow Brooks, New York: Osler is quoted as saying that angina pectoris under the age of 40 years is strongly indicative of syphilis. I take issue with this generalization. I have found it in youth to occur with acute infections causative of myocardial disease, such as scarlet fever, tonsillitis, rheumatism and influenza generally. It may, and does, occur with syphilis, however, and syphilitic angina is more common than we suppose, and escapes us because it is recognized only in the immediately premortem stage, and is not frequently enough confirmed post mortem, especially in private practice. I classify true angina pectoris as comprising those cases which have definite pathologic anatomy as their basis. My cases of angina pectoris are grouped as: (*a*) those caused by myocardial defects; (*b*) those caused by aortitis, and (*c*) those due to disease of the coronary arteries. Cases associated with syphilis also follow this classification. My estimate of syphilitic angina is a cautious one, because it is quite possible for a patient with active syphilis to have angina due to other causes. The series comprises no postmortem evidence, but I have endeavored to exclude all questionable cases. Nine instances of syphilitic angina pectoris were discovered in a total of 200 cases of angina pectoris. The oldest patient was 63; the youngest, 51. The average age was 52.6 years. Only one case occurred in a woman. In four instances a definite history of syphilis was obtained. In no case had early or thorough treatment been given. Angina never appeared less than twenty years after initial infection, which corresponds to other evidences of cardiac syphilis. Three patients had also marked generalized arterial disease, also probably syphilitic in origin.

In regard to the anatomic structure involved: Only two patients had aortic disease: dilatation and sclerosis of the arch with aortic endocarditis. Only one case evidenced positive myocardial disease. In two cases there were coronary emboli. In four the aorta and the heart muscle showed definite lesions. Three of these cases showed marked improvement under treatment. Both patients with coronary embolism died promptly. In the histories of all cases there was the factor of stressful life, emotional stress, and occupation carrying long continued nervous strain. Two instances showed hypertension and one, hypotension. In the others blood pressure was approximately normal. From a study of these cases it appears that typical angina pectoris is not a very frequent symptomatic manifestation of syphilitic cardiac disease, no more than with cardiac disease caused by other factors. I feel also that anginal symptoms do not usually occur as an early manifestation of syphilitic heart disease. The time has corresponded to the appearance of cardiovascular syphilis without angina.

Considerable benefit may be expected from vigorous and well adapted specific treatment. Symptomatic improvement may occur even in long standing lesions. As in other forms of syphilitic cardiovascular disease, treatment has been successful only in degree to the prominence given to the specific nature of the disease.

Jaundice and Liver Lesions in West African Yellow Fever

Dr. Oskar Klotz, Toronto: Yellow fever has a sudden onset with headache and prostration, vomiting occurring in the first twenty-four hours and persisting. Sometimes the vomitus is blood streaked or like coffee ground material. Albuminuria appears on the second day. Jaundice varies much. It is constant in some epidemics, but there is a variation in the period of time at which it appears. In many cases jaundice is fairly constant; it appears the third day and persists during convalscence. In the more severe cases, jaundice is delayed until the fifth to the seventh day, or it does not appear until convalescence sets in, when there is intense jaundice. In severe cases with intense intoxication, jaundice may not appear until the time of death and it is often more marked after death. There is also an odd leaden color accompanying the jaundice in severe cases. Studies were made on the tissues of thirty-five yellow fever cases. All cases showed a liver lesion—degeneration with evidence of intoxication of the parenchymatous tissues localized in the midzone of the lobule. The liver cells are destroyed or stand out as hyaline masses, not readily undergoing autolysis. The character of the cell change differentiates it from yellow atrophy and from the results of acute poisoning. The liver cell columns are picked out first. The stroma is intact. There is no thrombosis of the sinus. There is an acutely selective intoxication with reaction of the reticulo-endothelial Kupffer cells. The cells are actively phagocytic, and in seventy-two hours almost all the parenchyma of the liver is destroyed. The Kupffer cells also show severe degeneration with necrobiosis. The reticulo-endothelial cells are injured in other organs, such as the spleen. This looks as if the theory that the reticulo-endothelial cells play a part in the production of bile pigments is correct. When their function is markedly depressed, jaundice may be absent in this disease.

DISCUSSION

Dr. William H. Welch, Baltimore: I am interested to note that Dr. Klotz has brought out evidence that African yellow fever is truly yellow fever. There have been skeptics. Dr. Gorgas was one. He did not like the idea that efforts should have to be extended to the West Coast of Africa, because he had an ideal of extermination of the disease. I am familiar with these cases. Sternberg brought a great deal of valuable material to our laboratory to study. This thrombosis in the midzone of the liver is most interesting. We suspected that there were intracellular areas in the liver resembling protozoa. Methylene and eosin brought these forms out distinctly. It brought out the earliest cell inclusions. Councilman's work on the Kupffer cells, however, was the real contribution to the subject. Dr. Klotz has confirmed Hoffman's statement as to the calcifications in the renal tubules. These have been considered almost pathognomonic, but they may exist in other conditions. I think no one has gone ahead of Councilman's work.

Dr. Oskar Klotz, Toronto: I am in agreement with Dr. Welch in emphasizing the work of Councilman. Our work has been on that basis. The point Hoffman described is a characteristic lesion of the kidney—lime casts in the tubules. That was found in 60 per cent of the West African cases. It was identical with findings in Havana and in South America. These lime casts of the kidney tubules were found in cases of African plague and also in acute poisoning. We were not equipped to carry out blood chemical examinations. There is a better field for this research in western central Africa, where the disease exists in a sporadic form and also in epidemics in which about 1,000 cases occur among, perhaps, 5,000 inhabitants.

*Pyorrhea Alveolaris: Rôle of Certain Micro-Organisms Found in Lesions. J. H. Fisher, London, Ont.—p. 169.

Metastatic Endometriosis.—A histologic study was made by Sampson of sections of uteri removed during the various stages of the menstrual cycle, in which the veins had been injected with bismuth. By this means it was demonstrated that there are venous capillaries and large venous sinuses in the uterine mucosa and that the latter empty into similar sinuses (receiving) in the uterine wall. During menstruation, blood escapes from the mucosal vessels into the surrounding tissues, and bits of the mucosa are often set free in the extravasated blood. These studies suggest that this menstrual blood containing fragments of endometrial tissue at times escapes through a ruptured mucosal *sinus* into the venous circulation of the uterus. Sections of misplaced endometrial tissue, wherever situated and irrespective of its origin, also suggest that a like dissemination of fragments of this tissue occurs during menstruation.

Vascular Channels of Spleen.—MacNeal, Otani and Patterson propose a technic for the fixation and preservation of human spleens obtained by surgical splenectomy or at necropsy, which makes possible a more illuminating study of the structure of this organ. For the study of animal spleens a modified perfusion technic is described, in which the *perfusion fluid or experimental injection* material is introduced into a short gastric branch of the splenic artery.

Islands of Langerhans in Human Pancreas.—Otani asserts that the process of hypertrophy of the islands of Langerhans in the adult pancreas is mostly due to transformation and hyperplasia of acinar and centro-acinar cells, the hyperplasia of the island cells proper being relatively insignificant. The acinar cells are able to change into island cells, indicating a genetic relation between islands and acini. The new formation of the islands in the adult pancreas may occur by transformation and hyperplasia of the acinar, centro-acinar or duct cells.

Essential Suprarenal Insufficiency.—In the two cases reported by Medlar there was present a marked hyperplasia of the lymphoid apparatus, including the spleen in both cases and the thymus in the one case in which examination was possible. Neither case showed any clinical or pathologic evidence of hypofunction of the *gonads. In the case of the* female patient, pregnancy and healthy children had ensued. In the case of the male, the testes were functional and appeared normal in the gross and the microscopic examinations.

Pyorrhea Alveolaris; Bacteriologic Studies.—*Endameba gingivalis* was present in direct smears in 95.5 per cent of 201 cases of pyorrhea examined by Fisher. Evidence is submitted that this ameba is a harmless parasite. *B. fusiformis* and spirilla were found in the smears from all cases of pyorrhea studied, and in all the normal gums. *Streptococcus viridans* was present in each of thirty cases of pyorrhea examined culturally. Hemolytic streptococci were not present in any of the cases examined culturally, nor were hemolytic influenza bacilli.

Roentgen-Ray Anatomy of Alimentary Tract.—Todd made a roentgenologic study of the normal alimentary tract in healthy young male students. He says that all parts of the tract are exceedingly sensitive to emotional or nervous conditions. These influence different parts of the tract in divers directions. The stomach becomes atonic in outline, though not in movement or in emptying time. The duodenum shows pseudostasis. The transverse colon exhibits a spasm which may absolutely inhibit the onward passage of its contents. The sites of the cardia and pylorus are affected in similar manner, though *not so greatly as are the positions of the* greater curvature in the pyloric vestibule and the gastric tube. The normal position of the small intestine in the living individual, whether upright or horizontal, is in the lower abdomen and true pelvis; its disposition is in ladder coils. Peristalsis in the lower ileum may be exceedingly slow in spasm of the transverse colon, one wave taking half an hour to complete its cycle. The proximal colon (cecum, ascending colon, transverse colon) exhibits a peristaltic wave like those of the stomach and the small *intestine. Its rate of progress in the* transverse colon is about half that of stomachic peristalsis.

Cholecystography.—Sproull administers the dye in cream of wheat, giving 2 Gm. to patients of 150 pounds (68 Kg.) or under, and 3 Gm. to patients weighing more than 150 pounds. No special meal to empty the gallbladder is advised, and no cathartic preparation is given. The dye is dispensed to the patient in plain gelatin capsules, each containing 0.5 Gm. of the dye. At 8 p. m. all of the medicine contained in these capsules is added *to four (or six) tablespoonfuls of cooked* cream of wheat (cold). Nothing should be taken after midnight. At 8 a. m. films are taken, and the patient is dismissed until 1:30 p. m. with instructions to continue the fast from food and drink. At 1:30 p. m. the second series of films is taken, after which the patient is advised to eat a meal rich in fats, consisting usually of a dropped egg on buttered toast, a pudding with cream, and a cup of cocoa with cream, and to report two hours after for a third film. The method is said to yield excellent results. Of twenty-three patients studied, only three complained of nausea. Two vomited a little. Three had slight diarrhea. None were seriously inconvenienced.

Pineal Gland and Brain Tumors.—In endeavoring to establish a normal variation in the position of the pineal gland, Vastine and Kinney examined 350 skull films essentially negative for intracranial lesions. Two hundred of the films showed calcification of the pineal gland. The gland was displaced in 51 per cent of the patients with meningiomas. Acoustic neuromas were seen to cause displacement in 22 per cent of the cases. Hydrocephalus per se was observed to produce a displacement in 13 per cent of the cases. Pituitary adenomas were rarely seen to cause a change in position of the gland, displacement being observed in only 10 per cent of the cases. Intracranial hemorrhage caused displacement in two cases.

Staphylococcus Septicemia: Case. A. C. Reed and F. E. Stiles, San Francisco.—p. 492.

Chronic Appendicitis.—In Butka's opinion chronic appendicitis often is a clinical condition resting more on a functional than a pathologic basis. Obliterative and atrophic appendixes are the result of previous acute pathologic processes, and are not found in increased numbers in cases diagnosed clinically as "chronic appendicitis." The presence of eosinophils in the mucosa of the appendix is not an indication of chronic appendicitis, but is probably a link in the defensive mechanism and is normal. Eosinophils and leukocytes in the submucosa and muscularis are positive evidence of inflammatory changes in the appendix. Chronic appendicitis cannot be determined in more than an extremely small percentage of instances by the histologic examination alone. Complete data on gross conditions seen at operation are essential to a correct diagnosis.

Insulin Treatment of Diabetic Coma.—Fifty-three cases of diabetic coma are reported by Leake. Thirty-seven of these patients died. Eight died within twelve hours after admission. Twenty of the thirty-seven patients who died had grave complications, which were discovered at the time of examination or at necropsy. The highest blood sugar noted was 625 mg. per hundred cubic centimeters of blood; the lowest, 181 mg. Two patients had extremely low plasma carbon dioxide combining power, 9.9 volumes per cent; one recovered. One patient was admitted on three separate occasions in coma, recovery ensuing each time; another was admitted twice in coma, recovering each time, and one, a child aged 2½ years, died a few hours after his second admission for diabetic coma. Of the eleven patients who had been under insulin treatment prior to the onset of coma, only five recovered. The smallest quantity of insulin required to restore a patient to consciousness was 15 units in a child 2½ years of age. Many of the patients who received large doses of insulin remained stuporous for several days. Leake has found it unnecessary to administer more than 200 units to the average coma patient during the first twenty-four hours, but would not hesitate to give five times that amount if indicated. In addition to the liberal use of insulin, buffered with carbohydrate, the treatment of diabetic coma consists mainly in forcing fluids, warmth, elimination and stimulation with caffeine sodiobenzoate and digitalis. Not more than 25 Gm. of sodium bicarbonate should be administered daily.

Roentgen-Ray Treatment of Erysipelas.—Roentgen-ray therapy for erysipelas is regarded by Harbinson and Lawson as being a valuable form of treatment. Relief is obtained generally within twenty-four hours. The febrile period is shorter than in infections of equal severity treated by other measures, and the usual length of illness is shortened. There are, possibly, fewer complications and less chance of spread than in other forms of treatment. There is no pain or discomfort attending the treatment. Advanced, serious cases of erysipelas involving fairly large areas, with high temperature and general infection, may be treated successfully.

Back Injuries in Industrial Employees.—Herndon has made a study of 941 consecutive cases of back injuries in industrial employees. Sprain occurred in 498 cases. About two thirds of the cases were located in the lumbosacral region. In about 11 per cent the condition seemed to be localized about the region of the sacro-iliac joint. The next most frequent site was the middle and upper lumbar regions, where about a fourth of the cases occurred. Contusions occurred in 122 cases. Fracture of the vertebral processes occurred in forty-one cases. In thirty-six cases the fracture involved one or more of the transverse processes. In about half of these the fracture was due to abnormal muscular pull, and in about half to direct violence. Fracture of the vertebral bodies occurred in thirty cases, or 3 per cent. Many of these followed what seemed to be slight accidents, and were surprisingly devoid of symptoms. Chronic deforming arthritis was found in 107 cases. A neurosis was diagnosed in eleven cases. Malingering occurred in thirty-five cases. In ninety-seven cases, the condition of the back and the symptoms complained of seemed entirely attributable to disease. Variations in the spine from the normal or textbook anatomy occurred in 4.8 per cent of the cases in the lumbosacral region. The most common anomalies were split spinous processes, usually of the first sacral vertebra, and sacralization of the fifth lumbar vertebra.

Cause of Multiple Infective Arthritis.—Hadjopoulos and Burbank suggest that the main primary cause of chronic rheumatoid arthritis seems to be a highly selective group of streptococci. In the symptom complex of chronic rheumatoid arthritis, a secondary rôle may be played by diphtheroid bacilli, bacilli of the para-colon group, and *Staphylococcus aureus*.

Arthroplasty of Hip Joint.—Of fifteen arthroplasties for ankylosis of one hip done by Campbell, excellent results occurred in ten. In only two cases has ankylosis recurred. Of the ten with excellent results, ankylosis was probably caused in five by the gonococcus. In all cases there is stability, endurance and efficiency.

Experimental Transplantation of Suprarenal.—Jaffe asserts that the suprarenal cortex of the guinea-pig can be transplanted autoplastically into the abdominal wall and may remain for months, growing to fairly large size. It can be transplanted homoplastically but these transplants usually degenerate after a few months. Small autoplastic transplants are capable of maintaining the life of a completely suprarenalectomized guinea-pig for weeks, and large transplants maintain the animal indefinitely in good condition. Irritation phenomena follow the grafting of suprarenal cortex because of the entrance of epinephrine into this tissue during the manipulation involved in removal of the gland.

Experimental Atherosclerosis.—Evidence is presented by Shapiro which indicates that alimentary hypercholesterolemia acting over a sufficient period of time (in rabbits with all organs intact, 110 days or longer) causes deposition of cholesterol within the intima of the aorta. Deposition of cholesterol within the intima of the aorta initiates the formation of experimental atheromas. Thyroidectomy, splenectomy, and gonadectomy augment hypercholesterolemia, and thereby facilitate and accelerate the development of experimental atheromas of the aorta in rabbits. Sublethal suprarenal insufficiency does not increase the susceptibility of rabbits to the development of such atheromas.

Production of Purpura by Pneumococcus.—Julianelle and Reimann state that the purpura-producing principle of pneumococcus is nonantigenic in the sense that it does not stimulate the formation of antibodies. It does not exist preformed in the cell, but is rather an autolytic derivative, since it is formed only when pneumococci undergo autolysis, and is not found when the autolytic ferments are inactivated. The purpura substance is associated with the proteose fraction of active pneumococcus extracts.

Reticulo-Endothelial Cells Form Amyloid.—The facts presented by Smetana suggest strongly that reticulo-endothelial cells are actively concerned in the formation of amyloid.

Resistance to Flow of Blood by Lungs.—It is shown by Moore and Binger that the embolism of pulmonary arterioles and capillaries produced by the intravenous injection of starch grains results in a dilatation of the pulmonary artery and the right chambers of the heart.

Complement Fixation in Tuberculosis.—Lewis avers that the prolonged extraction of the tubercle bacillus with boiling ethyl alcohol, followed by one or more reprecipitations by chilling the hot alcoholic solution, easily yields a preparation very active as antigen in the complement fixation reaction. This preparation gives a precipitation reaction with a high dilution of the normal blood serum of a number of species. The precipitation reaction presents as a peculiar feature a very long prozone, and is further dependent on a preceding heat treatment of the serum for its demonstration. Since it occurs as a reaction of normal serum, the reaction is apparently not influenced by immunization sufficient to develop moderate specific complement fixation reactions.

Influence of Light on Transplantable Neoplasms.—Experiments are reported by Pearce and Brown in which an environment of constant and continuous light with a wave length from 3,022 to 5,790 angstrom units, supplied by mercury arcs in crown glass, and of constant darkness, have influenced the course and character of a malignant disease of rabbits induced by a transplantable neoplasm. Under the influence of constant light the level of malignancy was lower than in control animals living under ordinary conditions of diffused sunlight. Under the influence of constant darkness the level of malignancy was somewhat lower than in the control animals, but the effect of this environment was modified by the special character of the disease prevailing at this time. The incidence of bone metastases was unusually high, but it was greatly increased in the rabbits kept in constant darkness. These observations furnish experimental evidence in support of the belief that there is a correlation between the external factor of light and the manifestations of an experimental malignant disease.

Silicosis of South African Gold Mines: Changes Produced by Legislative and Administrative Efforts. W. Watkins-Pitchford, London.—p. 109.
*Experimental Electric Shock. R. W. I. Urquhart, Toronto.—p. 140.

Experimental Electric Shock.—The experiments made by Urquhart confirm the deductions of previous observers as to the cause of death in electric shock; namely, that it may be due to primary cardiac failure, to primary respiratory failure, or to a combination of both. In laboratory animals, when the current traverses the body from the head to a hind limb, about 45 per cent of the deaths are of purely cardiac origin. The remainder of the deaths occur because of failure of the respiratory movements. In these, as in the group in which the current is passed directly through the brain, a condition of profound paralysis or block becomes established in the respiratory, vagus and vasomotor centers. That the block involves these centers is shown by experiments which demonstrate clearly the absence in electrocuted animals of reflex effects normally functioning through them. Since the nerve centers become insensitive to extraneous influences, counter stimulation is not an aid to recovery. No definite histologic changes can be made out in the brain to account for the symptoms. The capillary hemorrhages which occur do not appear to be significant. These experiments also show definitely that when the electric current does not cause charring of nerve structures, the paralysis or block is recovered from and the reflexes return, provided efficient artificial respiration is applied. It is of the greatest importance that artificial respiration be applied early and be maintained for a sufficient length of time. Owing to the nature of the block in the nerve centers, the ordinary tests for death should not be accepted and "nothing less than cooling of the body or the onset of rigor mortis should be considered to be evidence of death."

Colonic Reaction in Food Allergy.—Eyermann reports a case with symptoms simulating gallbladder disease, but with evidences of allergy. The case was studied after the administration of whole wheat bread which never failed to produce gastro-intestinal symptoms, of which pain was the outstanding feature. These attacks were relieved by the hypodermic administration of epinephrine chloride, 1 : 1,000. The roentgen ray revealed spasticity of the colon, which was relieved by the hypodermic administration of epinephrine. Eyermann concludes that this case was one of hypersensitiveness affecting the intestinal musculature, and may be classified in the group usually known as intestinal or abdominal allergy Colonic spasticity may be a factor in the production of abdominal pain in this type of disorder.

Mercurochrome in Typhoid.—Saunders commends the intravenous administration of mercurochrome in the treatment of typhoid, combined with guaiacol inunction. Pure guaiacol rubbed into the skin, in the dose proportioned to age, and always followed by an oil rub to prevent irritation, he says, will reduce the temperature in typhoid and tuberculosis infection, and also in cases of uncomplicated pneumococcus pneumonia.

Sgambati Urine Test in Peritonitis.—The Sgambati reaction was applied by Kilduffe to a series of 571 albumin-free urines submitted for routine examination in an endeavor to ascertain whether positive reactions were to be found with undue frequency in the absence of peritonitis, and also, as opportunity offered, to determine the frequency with which it was encountered in the presence of peritonitis. The specimens were obtained from unselected patients with a variety of medical, surgical and gynecologic conditions. In 556 cases not showing clinical or other evidence of peritonitis, negative reactions were found in 554. The two positive reactions occurred in a case of gastric ulcer with hemorrhage in which clinical or other evidence of peritonitis was not obtainable This patient had repeated hemorrhages, as a result of which he died. There were fifteen cases of known peritonitis in addition to the cases noted above, in none of which a positive reaction was obtained.

*Pregnancy and Diabetes B D Bowen, Buffalo —p 351
Public Health Progress in Twenty Two Countries. E Parkhurst, Albany. —p 358

Stricture of Ureter.—Church presents an analysis of 100 cases of stricture of the ureter, and reviews the literature on this subject

Pregnancy and Diabetes.—In the seven cases reported by Bowen, five patients required insulin before, during and after pregnancy. In these five cases, pregnancy would have been impossible without insulin, as the diabetes was of several years' duration The two patients who did not need insulin were obese Bowen is convinced that diabetes complicated by pregnancy, particularly if the diabetes is mild, can be carried through successfully if the patient is kept under the strictest supervision. In the event of serious complications, the pregnancy should be terminated immediately, preferably by cesarean section

Acute Sphenoid Sinus Infections.—Mithoefer is of the opinion that acute sphenoid sinus disease is of frequent ocurrence, but because of the rapid and cursory examination of acute nasal infection an involvement of this cavity is often overlooked.

Oil-Ether Analgesia in Obstetrics.—Hoskins injects one-sixth grain (0 01 Gm) of morphine sulphate in 2 cc of a 50 per cent solution of magnesium sulphate. From twenty to thirty minutes later, a mixture of quinine sulphate, 10 grains (0 65 Gm.) ; alcohol, 2 drachms (7 5 cc) ; ether, 2½ ounces (75 cc), and olive oil, 4 ounces (120 cc.), is injected into the rectum by means of a large glass syringe to which is attached a number 17 size catheter. The latter, being well lubricated with petrolatum, is inserted from 4 to 6 inches into the rectum, the time consumed being from one to two minutes. As a rule, the patient is drowsy in from five to ten minutes, and in from fifteen to twenty minutes she is asleep. This form of analgesia can be used with comparative safety, hospitalization of cases not being necessary for its use. Labor, as a rule, is prolonged in multiparas, and also occasionally in primiparas. Most primiparas require two or more instillations if analgesia is to be afforded through the second stage of labor. The instillations are best omitted with multiparas, or else given in reduced quantity unless a prolonged or difficult labor is expected.

Presence of Aluminum in Blood.—Analyses for aluminum have been made by Mull et al. on the blood of thirteen miscellaneous hospital cases and on pig's blood. In all instances the amount of aluminum was less than 0.2 mg. per hundred cubic centimeters. When larger quantities of blood (from 10 to 30 cc.) were used, the results appeared to be somewhat lower. Excellent recoveries of added aluminum have been obtained.

Cough and Lung Abscess.—The experimental data reported by Van Allen et al. indicate: (1) that in dogs an infected embolus in the lung does not always result in abscess, at least when this strain of organism is used; (2) that the *disease is characterized by absence of cough and rapid healing*, and (3) that when the factor of cough is supplied, the cavities which form may be much larger and may persist much longer.

Skin Reacting Substances of Typhoid Bacillus.—Fleisher and Tierney report that following the injection of 0.1 cc. of the filtrate of a broth culture of typhoid bacilli intracutaneously in the arm of a human being, there appears in from twelve to twenty-four hours a reaction similar to that produced by the injection of *Streptococcus scarlatinae* toxin. The reaction fades after from twenty-four to forty-eight hours, but may leave a slight pigmentation. The reactions produced in subjects who neither had had typhoid nor were ever immunized against typhoid are very variable. No evidence of any ability to inhibit the local reaction was noted in persons who had had typhoid, or who had been immunized against typhoid. In individuals with typhoid, the reaction to the injection of the filtrate was markedly diminished (as compared with weakly reacting normal individuals) or was negative. During the early period of the disease the reaction might be distinct; in the second or third week the reaction was usually diminished or negative. After convalescence, the reaction began again to become positive. The ability of the organism to neutralize the local action of the typhoid filtrate was apparently evanescent, and confined to the actual period of the disease.

Fat Embolism.—Experiments are reported by Lehman showing that certain artificial emulsions can be broken down by the addition of necrotic muscle extract, peptone and histamine, besides other substances. It is emphasized that no significance has heretofore been placed on the physical state of the normal fat in the blood stream. The possible relationship of clinical fat embolism to the presence of protein split products in the blood stream is suggested by the breaking down of artificial emulsions by these substances.

Monilia and Pernicious Anemia.—This study made by Garcia et al. of the sugar fermentation reactions of the strains of *Monilia* isolated from cases of pernicious anemia shows that all act on dextrose, levulose, maltose, galactose, dextrin and sucrose. The action on lactose, mannite and insulin varies with the different strains. These reactions can be used to distinguish these organisms from various stock strains of yeasts. They resemble closely those given by the stock strains of *Monilia psiliosis*. *Monilia* isolated from other pathologic conditions seems, in general, closely related to the pernicious anemia strains in type of growth and fermentation reactions, although some slight differences are found in many strains.

Cholecystography and Liver Function Test.—Cole uses phenoltetraiodophthalein. The dose is 0.04 Gm. per kilogram of body weight, and is preferably given in the morning intravenously on an empty stomach. The dose need not exceed 2.5 Gm. Lunch should be omitted, but if hunger demands, the diet should be limited to liquids without fats and low in proteins. Water is allowed. Roentgenograms are taken four, eight and twenty-four hours after the injection. A specimen of blood is taken before giving the dye, and one-half hour afterward. Retention of less than 15 per cent of the dye in the blood serum one-half hour after injection of the dye, and less than 4 per cent one hour after injection is considered normal. Retentions of any greater amounts for the specified time are considered abnormal. The largest amounts of retention have been found in patients having cirrhosis with ascites, and may be as high as from 80 to 90 per cent one-half hour after injection. Retentions almost as great have been seen in patients having acute hepatitis with cholangitis, usually with slight jaundice. A mild retention above normal, ranging between 17 and 35 per cent, is found in cases of cholecystitis.

Immunity to Measles.—Musser states that the toxic filtrate of a bouillon culture of organisms isolated by blood culture when injected intradermally into susceptible individuals causes a transient erythema, whereas in persons who have had measles, the skin reaction is negative. This is confirmatory proof that there is a specific, now isolated, organism of measles which produces a toxin that may be used as an index of immunity to the disease.

Etiology of Measles.—In the cultures prepared by Duval and Hibbard from the blood of six patients with measles, a small gram-positive diplococcus was recovered in pure culture on sheep serum agar. The cultivated coccus completely corresponds in all six instances, and also to that of Tunnicliff. In no instance was there encountered any micro-organism other than the coccus described.

Experimental Carcinoma.—Histologic pictures like those of cancer have been produced by Harris by causing deranged epithelial cell relationship through nipple and gland inversion, although its nodules have thus far not demonstrated the usual functional activities of cancer.

Carbohydrate Metabolism After Suprarenalectomy.—The Coris failed to find any marked difference in the carbohydrate metabolism of normal and suprarenalectomized animals. Emphasis is laid on the fact that the inhibition of glycogen synthesis in the liver of insulinized animals is not due to the action of epinephrine. Insulin injections have also been shown to cause a diminution of liver glycogen in animals in the postabsorptive state. A repetition of these experiments on suprarenalectomized mice gave the same result. This phenomenon is, therefore, not connected with an increased discharge of epinephrine.

Bacteriologic Studies of Acute Rheumatic Fever.—From the blood, tonsillar crypts, abscesses, heart vegetations, feces and urine from persons with rheumatic fever and the allied forms of this protean disease, Birkhaug has isolated a new type of nonmethemoglobin-forming streptococcus which constitutes a closely related group of micro-organisms, distinguishable from the *Streptococcus viridans* and *Streptococcus hemolyticus* groups. Among sixty-eight strains of the nonmethemoglobin-forming streptococcus isolated from rheumatic fever, forty-nine strains, or 72 per cent, were found to produce a demonstrable soluble toxic filtrate, slightly weaker in toxicity than that obtainable from *Streptococcus erysipelatis*. About 15 per cent of persons without a history of rheumatic fever, and from 56 to 76 per cent of persons with a history of rheumatic fever gave positive skin reactions within twenty-four hours after the injection of this filtrate. Intravenous and subcutaneous injections in the rabbit of the living nonmethemoglobin-forming streptococcus invariably produced a nonsuppurative polyarthritis, with marked swelling of the joints. Subacute bacterial endocarditis and myocarditis, with a unique and regular tendency to vegetative mitral stenosis, extensive mural vegetations, and occasionally pseudonodular arrangements of multinucleated forms of leukocytes, as well as of polymorphonuclear and mononuclear cells, were encountered. Intravenous and subcutaneous injections of the sterile toxic filtrate rapidly developed polyarthritis of the nonsuppurative form, after repeated injections of increasing doses. The only changes found in the heart of the rabbits injected with the sterile toxic filtrate were those of myocardial degeneration.

Destruction of Botulinum Toxin by Bacteria.—Sherman et al present data which indicate the destruction of botulinum toxin by *B. coli*, *B. communior*, *B. aerogenes* and *Proteus vulgaris*

Insulin Keeps Depancreatized Dogs Alive.—A number of dogs totally deprived of the pancreas and fed on meat have been kept alive by Murlin for periods of from six weeks to four months on daily doses of from 40 to 100 clinical units of insulin in blood serum administered carefully by stomach tube in such a way as to preclude the possibility of absorption from the mouth The effect on respiratory metabolism is immediate

Lymphocytes and Macrophages.—The possibility of the transformation of a small lymphocyte into a macrophage (polyblast) and further into a fibroblast is demonstrated by Maximow.

Magnesium Sulphate Lowers Mortality of Thyroparathyroidectomized Rats.—The high death rate among thyroparathyroidectomized rats is reduced by Jung and Cook by the intraperitoneal injection of magnesium sulphate For a rat weighing 150 Gm, the injection consists of 5 cc of a 1 per cent solution of the crystalline salt Experience has shown that asepsis is unnecessary A normal rat can easily tolerate as many as five hourly injections of this quantity After each injection, manifestations of the well known anesthetic and curare-like actions of magnesium are noted

Effect of Venostasis on Heart Failure.—Danzer checks the circulatory overflow in the periphery by the compression of the veins in the four extremities This is conveniently performed by applying four blood pressure cuffs around the extremities as near to the trunk as possible. These cuffs are all in series and connect with an ordinary blood pressure manometer and rubber bulb The apparatus is termed the "venostat" The cuffs are gradually inflated up to diastolic pressure, and maintained at this level for from ten to twelve minutes They are then very gradually deflated The application of this procedure during a cardio-asthmatic attack relieves the symptoms in about five minutes, and frequently terminates the attack by the time the treatment has been completed Objectively, sonorous and sibilant rales that may be present over the lungs become very faint or disappear entirely In the belief that venostasis unloads the heart sufficiently for recuperation, its effect was tried on clinical cases of heart failure in which large doses of digitalis were required Only far advanced cases were studied Digitalis was not given, and no other treatment besides the restriction of salt and fluid intake was applied Venostasis was produced for from ten to twelve minutes every two hours Marked improvement in the dyspnea resulted Orthopnea disappeared The edema lessened and the water excretion increased—in some cases, it exceeded the fluid intake After a week, however, digitalis had to be given again because of the return of the edema Danzer believes that venostasis is capable of disembarrassing an insufficient heart, and that only in the far advanced cases must digitalis, in addition, be given.

Filtration Experiments with Bacteriophage.—Experiments done by McKinley and Holden indicate that a particular substance such as the bacteriophage is filtrable from the cerebrospinal fluid to the blood stream in rabbits, but not from the blood stream to the cerebrospinal fluid

Liver Injury in Acute Alcohol Poisoning.—The indirect van den Bergh quantitative test for bilirubin, and the quantitative determination of urobiligen in the urine, were applied by Wallace in seventeen cases of acute alcoholic poisoning. There was found an increase in the amount of bilirubin in the blood serum, which persisted for four or five days, with a gradual decline to the normal. Estimations were made. An increase in urobiligen was found ranging in dilutions from 1:90 to 1:350 The urobiligen curve closely corresponded to the bilirubin curve This increase of both bilirubin and urobiligen was directly proportionate to the severity of the poisoning. It is concluded from these observations that in acute alcoholic poisoning there is definite evidence of liver injury, and that this is proportionate to the severity of the poisoning.

Pharmacology of Ergothioneine.—The negative results obtained by Tainter support the earlier conclusion that this substance does not have well marked pharmacologic actions.

Pollen Proteins.—Bernton et al. found that the toxic action of pollen on susceptible individuals is not restricted to the albumin Cutaneous testing has demonstrated a sensitivity of patients to one or more proteins isolated from pollen.

Vegetal Bronchitis.—Stiles points out that the systematic enlightenment of parents and nurses, as well as misguided friends and strangers, to the danger of giving peanuts, watermelon and similar substances to young children would materially reduce the number of these cases. If left untreated, these cases are almost invariably quickly fatal, but if subjected to early bronchoscopy, the prognosis is distinctly favorable

Syphilis of Urinary Bladder.—The six cases observed by Turner have all been tertiary manifestations of the disease: four ulcers and two papillomatous masses with disintegrating processes going on in one. In all cases there was a positive Wassermann reaction; yet all but one patient gave a negative history of syphilis. The symptoms in each case were alike with respect to cystitis, frequency, pain and slow onset.

Primary Pulmonary Teratoma.—This case is reported by Slaughter and Stephens as one of primary pulmonary teratoma of a malignant character, which most likely originated from the pleura in the interlobar space between the upper and lower lobes of the left lung, and invaded both the mediastinum and the left lung.

Treatment of Yaws and Syphilis in Haiti.—The treatment given at the Haitian General Hospital for syphilis and yaws consists of 1 grain (0.065 Gm.) of mercury salicylate in a suspension of liquid petrolatum given intramuscularly each Tuesday, and 1 grain (0.065 Gm.) of sodium potassium bismuth tartrate in 2 cc. of freshly distilled water given intramuscularly each Thursday. The sodium potassium bismuth tartrate contains 67 per cent of bismuth. Middlestadt reports the following results: in 60 per cent of the cases, a negative Wassermann reaction; in 16 per cent, a reduction to 1 plus; in 8 per cent to 2 plus, and in 2 per cent to 3 plus; in 14 per cent the reaction remained unchanged. There were four cases of abscess formation. It was found that these conditions were relieved by giving the same amount of the salt in 2 cc. of distilled water instead of 1 cc.

Diathermy in Shock.—Cottle's patient recovered from a most extreme degree of shock resulting from an automobile accident in which he sustained a compound fracture of the leg bones. It is believed that diathermy to the liver region contributed largely to this recovery.

Spontaneous Rupture of Heart.—Cooper reports two cases. In the first case the cause of death was obscure. A necropsy was performed, and the anatomic diagnosis was nontraumatic, spontaneous rupture of the left ventricle of the heart. The contributory cause was chronic myocarditis, with marked fibroid and fatty degeneration. In the second case, the chief complaint was soreness in the chest and cough. The diagnostic impression at the admission examination was chronic myocarditis with passive congestion of the liver, angina pectoris, and arteriosclerosis. The roentgen-ray report showed fusiform dilatation of the aortic arch. The patient died on the morning of the fifth day. At the necropsy, healed tuberculosis of the lungs, chronic diffuse nephritis, arteriosclerosis, coronary sclerosis and occlusion, and spontaneous rupture of the left auricle of the heart (multiple) were found.

Mercurochrome Treatment of Acute Gonorrhea.—The method of treatment with mercurochrome devised by Potter and Redewill was tried by Williams and Cooper in twenty-five cases. Following the injections there was a uniform change in the leukocytes, consisting of a negative phase in which all types of cells, except the eosinophils and lymphocytes, decreased, followed by a positive phase in which these cells decreased and the other cells and the total white count increased. An artificial immunity to infection is apparently established by the injection of these substances, as was evidenced by a rise in temperature, a negative phase followed by positive phase, and an appreciable leukocytosis lasting for some days. Practically the same results were obtained with mercurochrome and milk, without the addition of sugars, but it is recommended that the latter be employed as a protective agency against possible anaphylactic shock.

Glandular Fever.—A clinical case of glandular fever is reported by Yanquell, which is quite unusual in that the inguinal glands were the only ones of the superficial groups involved.

Acquired Hydrocephalus.—In the case reported by White, there was no history of any primary condition, and the complete history of the case comprised only the symptoms of a gradually increasing intracranial pressure. It was only at the necropsy that evidence of a tuberculous meningitis was discovered.

Carcinoma of Stomach and Retroperitoneal Space.—Carcinoma developed in a young man, aged 27; the origin was apparently in the stomach, and the tumor extended through the stomach wall and formed a huge mass in the retroperitoneal space, continuous with the tumor area of the stomach. There were multiple metastases to the liver, gastrohepatic omentum, retroperitoneal glands, and the mesentery. In spite of the huge size of the tumor there were no growth symptoms, and the tumor was not noticed until one month before death; anemia was not present. It was impossible to determine the length of time this tumor had existed, but it certainly was not of recent origin, as there were large necrotic areas with considerable fibrosis.

Methenamine in Meningeal Infections.—It is shown by Brunschwig that methenamine, when administered by mouth in sufficient doses, readily passes into the cerebrospinal fluid. But here free formaldehyde is not liberated, nor does the drug exert antiseptic powers.

Reinfection in Syphilis.—In Archambeault's case the first infection was probably extragenital. Both infections were believed to have been innocently acquired. There were two primary lesions in the second infection.

Curious Case of Bullet Wound of Jaw.—Goldberg's patient was hit in the upper jaw by a bullet. He lost consciousness for two or three minutes. He expectorated a little blood for about thirty minutes. Both central incisors and the right upper canine were broken off at the gum border. The tongue was slightly lacerated in the median line for a distance of one-half inch. The bullet passed through the posterior pharyngeal wall just to the left of median line, and had its exit 1 inch to the left of the sixth cervical vertebra. Except for the loss of three teeth, this patient has no defects in speech, mastication or sensation.

Early Symptoms of Brain Tumor.—The four cases of brain tumor reported by Carlisle tend to indicate that the patient's first symptoms for which he is hospitalized may strongly suggest a psychoneurosis of a neurasthenic type; namely, "stomach trouble"; a generalized complaint that "health is failing"; vague disturbances of vision usually dismissed as refractive errors, and complaints of rather mild headaches and a feeling of inability to go on working as usual. Any patient with psychoneurosis of the neurasthenic type, with symptoms relating to the eye and stomach, and with head sensations, including visual hallucinations (especially when on a nontoxic basis), should receive sufficient observation and later reexaminations to exclude or include the triad—choked disk, the vomiting due to an organic brain lesion, and headaches from organic brain lesions (with or without an actual psychosis). Among the earliest symptoms which may make a definite impression on an examiner is that of a visual hallucinosis.

Etiology of Neurasthenia.—Sharp and Visher assert that the so-called functional disorders of irritable heart, pseudo-angina pectoris and paroxysmal tachycardia; irritable colon, constipation, and flatulence; hypotension, hypertension, and angioneurotic edema; menstrual difficulties and disorders of the sexual function, are especially likely to be accompanied by neurasthenic symptoms. Ill defined endocrinopathies, blood dyscrasias, diseases of the genito-urinary tract, quiescent tuberculosis, early diabetes, and focal infections are also frequent etiologic factors.

Experimental Kala-Azar—Sixty experimental animals, subjected to 184 bites from a minimum of 152 *Phlebotomus argentipes* known to be infected with *Leishmania donovani*, have not, in any case, developed kala-azar The presumption of Shortt et al is not that *Phlebotomus argentipes* cannot transmit the disease by its bite, but that the experimental animals used were not sufficiently susceptible to *L donovani* to become infected, except as the result of a more intensive exposure to infection than that to which they were subjected in the experiments

Effect of Quinine on Phosphorus Metabolism.—The results obtained by Hughes and Shrivastava show that quinine in antimalarial doses in man causes a retention of phosphates This fact is evidence of the interference of this drug with the carbohydrate metabolism This interference takes the form of causing an increased output of insulin Therefore, when quinine is administered in large doses over long periods, as is often done in the treatment of malaria, it is acting more or less continually as a stimulant of the pancreatic islets, and as overstimulation of this tissue is known to produce exhaustion, it is not unlikely that in many cases quinine plays a role in the production of a diabetic condition

Nutritive Value of Wheat—McCarrison's experiment demonstrates the high order of the nutritive value of whole wheat and the comparatively low order of the nutritive value of whole rice, a value which depends not only on the quality of their proteins but on their content of vitamins and of certain mineral salts of which one is manganese A diet of whole wheat sprouted grain milk, milk products and green leafy vegetables with meat occasionally, is one on which Indians flourish best and attain to the highest degree of physical efficiency encountered in that country

Effect of Manganese on Growth—McCarrison concludes that the growth promoting properties of whole wheat are in part due to the content of manganese in this cereal However a concentration of one part of manganese to 12 600 parts of food exercises a progressively increasing and retarding influence on growth whereas a concentration of one part of manganese in 617 700 parts of food exercises a markedly favorable influence on growth

Good Diet and Bad One.—McCarrison says that a diet composed of whole wheat milk milk products, sprouted legumes uncooked vegetables and fruit with fresh meat occasionally far surpasses in nutritive value that composed of white bread tea sugar margarine, jam, boiled vegetables and tinned meat to which the common food preservatives—boric acid, formaldehyde vapor and sulphurous acid—are added The former promotes physical efficiency and health, but the latter gives rise to stunting of growth, to physical inefficiency and oftentimes to disease The maladies of which the bad diet is so apt to lay the foundation are lung and gastro intestinal disease

Influence of Syphilis on Leprosy.—Lloyd et al assert that any nonspecific reactions in the latter stages of leprosy are due to experimental factors and are not caused by reagins comparable to those responsible for complement fixation in syphilis They will not, therefore, serve as a basis for any specific serum test for leprosy

Epidemiology of Cholera.—By means of the "open-bowel" method of culture which was devised by them, Tomb and Maitra have been able to prove that in many localities of an endemic area as many as 35 per cent of the inhabitants are chronic carriers of nonagglutinating vibrios. Efforts to demonstrate the identity of agglutinating and nonagglutinating vibrios found in cases of clinical cholera, while proving that the two vibrios are closely allied serologically, were, however, inconclusive and inconstant in results. Extended examinations of the stools of convalescent patients with epidemic cholera showed that 80 per cent of these persons became chronic carriers of nonagglutinating vibrios, the agglutinating form permanently disappearing in from two to four weeks. After examination of thousands of stools, the authors have been unable to discover one permanent carrier of agglutinating vibrios, and no such carrier has ever been reported by any other observers elsewhere. They therefore conclude that the nonagglutinating vibrio (which is itself capable of causing clinical cholera) takes on the agglutinating characteristic under certain biochemicophysical conditions in the human intestine, the nature of which is at present unknown, and that this mutation or epidemic form is the cause of epidemic cholera. Nonagglutinating intestinal vibrios constitute the reservoir of cholera both epidemic and endemic, the degree of nonagglutinability in a vibrio apparently depending not only on the nature of its surroundings but also on the period of time which has elapsed since it last existed in agglutinating or epidemic form. The nearer to the threshold of agglutinability a nonagglutinating vibrio is, the more closely would it seem to be allied both serologically and epidemiologically to the agglutinating vibrio.

Staining Tubercle Bacilli.—Shunker endorses the use of a half saturated watery solution of picric acid as a counterstain instead of methylene blue. The advantage of the method lies in the fact that the red stained tubercle bacillus shows up much better against a yellow background than a blue one, and it appears to have the additional property of restoring the color to feebly acid-fast bacilli, which would otherwise be invisible or unrecognizable.

Berberine Sulphate in Oriental Sore.—Varma injects 0.25 Gm. of berberine sulphate in 1 cc. of distilled water into the sores. This is followed by some local reaction in the form of congestion and edema, but with very little pain and tenderness, all of which subsided within four days. A week later the infiltration is repeated. A third injection is not required.

Treatment of Ascaris Infestation.—Row gave his patient 5 grains (0.32 Gm.) of santonin. The boy passed round worms both orally and by rectum for a week, the total number passed being 164. A second dose of santonin was given on the fourth day in order finally to eradicate the infection, and the patient made an uneventful recovery.

Large Ovarian Cyst.—The tumor in Pillai's case weighed 20 pounds (9 Kg.). It was a large multilocular cyst of the left ovary.

Irish Journal of Medical Science, Dublin

*Case of Salpinovesical Fistula. A. H. Davidson.—p. 159.
Antepartum Hemorrhage. L. Cassidy.—p. 161.

Structure of Ripe Human Ovum.—Dixon reports the examination of a ripe human ovarian follicle containing an oocyte in which the first polar body was present, and in which the chromosomes of the remaining nucleus were in the metaphase of the mitosis which would have given rise to the second polar body. The specimen was removed during the course of an operation from the body of a young adult woman.

Polar Bodies and Sex Determination.—Through a study of the spermatogenesis of man, and a comparison of this with the sperm formation and oogenesis of lower mammals and invertebrates in general, Gatenby has shown that in human beings sex determination is caused by the spermatozoa, which are of two types. The eggs are all the same so far as sex is concerned, and during polar body formation the two large sex chromosomes are separated, one going to the egg, one to the polar body. In this case, also, one gets the accidental segregation of the maternal father's or mother's sex chromosome in the egg. Thus, at polar body formation, it is determined whether the new child will have those qualities which are sex linked which come from the maternal grandfather or the grandmother.

Epistaxis Symptom of Toxemia of Pregnancy.—The epistaxis in this case was severe and could not be checked; hence, Solomons and Wilson decided to do an abdominal hysterotomy under stovaine anesthesia in the twenty-ninth week of pregnancy. A living fetus was extracted, but it died on the following day. The mother recovered.

Plugging Ruptured Uterus.—Solomons suggests that the treatment of ruptured uterus by plugging the rent with gauze, according to Tweedy's method, be applied more often instead of laparotomy.

Salpingovesical Fistula.—In Davidson's case tuberculous disease of the uterine adnexa caused adhesion to the bladder, with the establishment of a fistulous communication later. Davidson found only three similar cases on record.

Treatment of Neurosyphilis.—Birley expresses the belief that arsphenamine and its allied compounds, in the treatment of syphilis, other than in the Wassermann negative primary stage, has not succeeded in protecting the human nervous system from syphilis; on the other hand, there is no evidence that it has increased the incidence of neurosyphilis. The influence of arsenical compounds in modifying the incidence, time of onset and character of neurosyphilis remains to be determined. The pathologic changes that occur in the nervous system, including its coverings, and in the cerebrospinal fluid, from the time of infection up to the development of late parenchymatous neurosyphilis, and the mutual relations which exist between these changes, are still largely a matter of conjecture. The value of antisyphilitic treatment in arresting the progress of tabes and allied conditions is difficult to estimate, owing to their liability to undergo spontaneous arrest. The Wassermann reaction is not biologically specific, and its value as a guide to and indication for treatment cannot, therefore, be regarded as absolute. The nonspecific treatment of general paralysis has, according to the published figures, achieved better results than any previous method. A majority of the unsolved problems of syphilis are

[illegible] Medical College

intimately bound up with the increasing immunity to syphilis of the civilized peoples, together with the lack of any method by which this immunity can be estimated.

Cardiac Dyspnea.—The study of arterial blood in nineteen cases of cardiac dyspnea leads Fraser to the conclusion that (*a*) in cases of extreme congestive failure and of pulmonary disease in addition to heart failure, faulty elimination of carbon dioxide and faulty absorption of oxygen in the lungs may be factors in the production of increased respiratory activity; and (*b*) in patients near death, retention of fixed acids and raised hydrogen ion concentration may be factors in the production of increased respiratory activity, but that (*c*) in cases of cardiac dyspnea other than these, the condition of the arterial blood cannot account for the dyspnea, and is, indeed, indicative of the presence of increased pulmonary ventilation to which the changes in the arterial blood are secondary. Since the changes in the arterial blood due to the conditions (*a*) and (*b*) would mask the effect of such increased ventilation, it is reasonable to suppose that there is a cause of increased respiratory activity present in all cases of heart failure, which is independent of the quality of the blood supplied to the respiratory center

Chlorides of Gastric Contents.—According to Miller and Smith, the mean curves of total chlorides in all grades of gastric acidity are similar in shape, differing only in magnitude. The mean curves of the inorganic chlorides have the same general form and relation to time of digestion as those of the total chlorides, but agree much more closely in magnitude In hyperchlorhydria, the inorganic chlorides tend to remain low or to rise only very slightly. On the basis of the figures of the chlorides, there does not seem to be a clear definition of the so-called achylia of Addison's anemia, as distinct from other cases of achlorhydria

Postpartum Avulsion of Uterus—The case reported by Boggon is of interest, as it reveals how completely a woman may recover from the effects of so serious a disaster as the tearing out of the whole uterus after delivery. Four previous confinements had been normal. In the last confinement, the placenta was removed manually. In addition, there had been two miscarriages. The medical man had apparently been called in when labor was well advanced He found a breech presentation The membrane ruptured early, and a full-time living child, stated to be 12 pounds (5.4 Kg.) in weight, was born after a normal labor of eighteen hours. There was some delay in the birth of the placenta, and when it did come "the uterus, placenta, and a tumor were so inextricably mixed up and the neck of the uterus was so friable" that the attending physician "removed them all" by cutting through such attachments as remained. On the third day after delivery, the physician requested the admission of the patient. She did not complain of great pain, but had a certain amount of abdominal discomfort together with severe thirst. The abdomen was slightly distended in the lower part and tender; the uterus was not palpable. There was a bloodstained discharge, not much more in amount than the normal lochia, and not offensive. As there was no hemorrhage, and it was three days since delivery, the patient was merely given a sedative and propped up in bed. On the following day, she complained of abdominal pain. A constant flow of bright blood from the vagina, accompanied by a rise in the pulse rate, indicated the need for further investigation. At the top of the vagina was a ragged hole with coils of intestine lying above. On the right of the tear was a piece of decomposing muscular tissue, about 1 inch square, apparently all that remained of the uterus. The hole in the vault and the vagina were lightly plugged with gauze wrung out of 1:1,000 solution of formaldehyde and the patient was put back to bed. There was no further bleeding and the plug was removed four days later. The patient made an uneventful recovery.

Petechial Hemorrhages on Lungs and Heart of Unborn Child.—Smith reports the case of a young woman, from eight to eight and a half months pregnant, who received a blow on the head from a heavy stick and died shortly after. The following day, the fetus was removed from the uterus. On examination of the thoracic organs of the child, numerous petechial hemorrhages were observed on the anterior surface of the heart and aorta, and over the right and left lung. They were scattered over the whole surface of the lung, but were more intense on the surfaces in contact with the heart and on the interlobar surfaces. The hemorrhages varied in size from small pin-pricks to spots the size of a pin's head. The surface of the left lung had a slightly mottled appearance in the upper lobe, as a whole, the lungs looked as though they had never respired. They sank when placed in water. On microscopic section, no trace of vesicles could be observed, but under the pleura and scattered throughout the whole of the lung tissue there were numerous hemorrhages. These were by no means petechial, but took up quite a large part of the section. Numbers of greatly dilated capillaries could be observed, and these were in many cases surrounded by blood. In certain places, hemorrhages could be traced from the lung tissue to the pleura. There was no sign of organization of the blood or other change in the tissues of the lung. The other organs of the child and the organs of the mother were healthy.

The Non Acid Resisting Phase of the Tuberculous Micro Organism. J. Reenstierna—p. 309.
New Experimental Researches on Hemolysis. H. Diacono.—p. 318.

The Filtrable Form of Bacillus Pestis.—Burnet experimented with filtrates of organs removed from rats and guinea-pigs dead from plague. Cultures of *Bacillus pestis* were obtained with three filtrates. One filtrate caused plague infection in the guinea-pig. The results proved that search for filtrable forms of bacteria should be made not in preserved cultures, but in infected animal tissues at the phase of suppuration or autolysis The filtrable form of *Bacillus pestis* appeared as a granule proceeding from lytic disintegration of the bacillus. These filtrable forms present an analogy to that of the tubercle bacillus, probably also to those of the dysentery and of the typhoid bacilli.

Search for Bacterium Melitensis in Domestic Animals.—In his research, Torstenson used the blood and organs of twenty-three domestic animals living in contact with goats. Some of the latter were infected with *Bacterium melitensis*. The seroreaction and the cultures were negative. This shows that domestic animals, usually sensitive to melitensis inoculation, resist natural infection with the bacterium.

Deep Roentgenotherapy in Tumor of the Mediastinum. J. Pierquin and G. Richard—p 412
Roentgen Ray Treatment of Laryngeal Lymphocytoma. P. Cottenot.—p. 434.

Embolic Form of Acute Secondary Carcinomatosis of the Lungs.—The case described was in a man, aged 45. The disease started with symptoms of gastric ulcer, developing gradually into those of cancer. Phenomena on the part of the lungs appeared six years later. The association of obliterating phlebitis with signs of recurring pulmonary infarction suggested, Loeper and Turpin say, the diagnosis of embolism of the lungs. The patient died after four days. At necropsy, miliary and nodular carcinomas were found in the lungs, without any traces of infarction. The coexisting congestion and edema were probably a factor in the pathogenesis of the pulmonary syndrome. Obviously the phlebitis was caused by the primary tumor.

Beneficial Effect of Insulin in Arteritis Obliterans.—Yacoël and Boyer's case of nondiabetic arteritis obliterans was reported by Ambard, Boyer and Schmidt six months ago, when the patient, a man aged 36, had been under insulin treatment for six months. Rapid disappearance of the pain was then noted. Yacoël and Boyer now give further results of the treatment, which consisted in daily injections of 15 units of insulin. The patient is walking and has resumed his usual occupation. The oscillometric index rose from 3 to 5.5 within the last three months, evidencing increased permeability of the arteries. Yacoël and Boyer consider chronic arteritis obliterans as a local trophic disturbance in which other endocrine glands besides the pancreas may be involved. The influence of insulin is thus explained. Several similar cases are under treatment with insulin at the present time. Great improvement is manifest, although the treatment has been given for only a few months.

Bronchiectasis Following Pleuropulmonary Sclerosis. E. Sergent et al. —p. 371.

Normal and Pathologic Factors Influencing the Age at Which Children Start to Walk.—Variot's statistics are based on 490 observations. About 67 per cent of the children began to walk when they were between 11 and 14 months old. Their height was then from 71 to 76 cm. The weight at birth was from 3,000 to 3,500 Gm.; when they started to walk it was from 9 to 9.6 Kg. A connection between the weight or height of the infants and the age at which they began to walk was not apparent. Of the children who were fed exclusively on mother's milk, 82.8 per cent began to walk between the eleventh and fourteenth months; in infants fed first on mother's milk and later artifically, the percentage was 68.58; the percentage in infants who were entirely bottle-fed was 61.45. Most of the children had six or eight teeth when they started to walk. The rôle of sex proved insignificant. Acute diseases, atrophic rickets, and syphilitic, tuberculous or alcoholic heredity retarded walking. The same was observed in regard to congenital or acquired diseases of the nervous system.

Benzocinnamic Ester in Treatment of Pulmonary Tuberculosis. J. Jacobson.—p. 418.

Association of Purpura with Ganglionic Lesions.—In a case of fatal hemorrhagic purpura in a woman, aged 38, lesions of the lower spinal and the upper dorsal ganglions, of considerable extent, were discovered at necropsy by Mironesco and Perlstein. Chromatolysis of the nervous cells, increase of interstitial tissue and vascular hyperemia were found. Otherwise the neuraxon was intact. Symmetric location of the skin lesions suggested the theory that the pathologic changes in the ganglions might have been a factor in the disease.

Spectroscopic Evaluation of Bengal Rose in the Blood.—Snapper and Spoor point out the fact that colorimetric evaluation of bengal rose in the blood used in liver function tests may sometimes be misleading. This occurs in cases in which hemolysis is present. The pink hue of the bengal is then superposed on the red hue of the hemoglobin. To remedy this, the authors suggest a spectroscopic method of evaluation of the dye which, they say, is simple and rapid. Withdrawal of blood for control, which precedes injection of the bengal rose in the colorimetric method, is superfluous in the spectroscopic method. The details of the technic are given.

Chronic Endocarditis of Nonvalvular Origin. A. Landau et al.—p. 484.

Edematous Form of Arteritis in the Lower Limbs.—Harvier and Lemaire describe two cases of arteritis in the lower extremities, in which unilateral edema was the only clinical manifestation. The edema was accompanied by a high local temperature. In one instance, profuse sweating in both limbs preceded the edema by a year. Slight hypertension and increase in the oscillometric index coexisted with the edema. All the morbid signs testify to changes involving a part of the sympathetic. The changes may be connected with irritation of the arterial sheath, favored by walking and fatigue.

Ergotamine Exerts an Inhibiting Action on the Sympathetic.—Dreyfus summarizes the researches made by various authors on ergotamine. He concludes that the inhibiting action of the alkaloid on the sympathetic nervous system is incontestable. Therefore ergotamine should be used in all cases in which sympathicotonia is present. It is especially indicated in preoperative and postoperative treatment of exophthalmic goiter. From two to five tablets, each containing 0.001 Gm. of ergotamine tartrate, are given daily for a week. The treatment may be repeated once or twice at from three to five day intervals.

Pernicious Anemia and Gastric Ulcer. P. Carnot et al.—p. 338.

Cases of Pyloroduodenitis: Its Pathogenesis.—Bouchut and Ravault call attention to a disease the syndrome of which resembles surprisingly that of gastric or of duodenal ulcer The lesions in this instance consist of parenchymatous and interstitial inflammation of the pyloric and duodenal mucosa It is probable that many supposed ulcers of the stomach, subsiding in a few weeks under medical treatment, are nothing else than pyloroduodenitis The theory is that the latter is caused by primary infection of the mucosa by a micro organism the character and manner of invasion of which are still unknown Improper alimentation and alcoholism are adjuvant factors The pyloroduodenitis may prove to be a preulcerous stage of gastric ulcer Operation is justified only if diet and persistent medical treatment fail Two of seven cases observed are described

Role of Kidneys and Suprarenals in Diphtheria A Ravina —p 438

Sclerosis of the Island of Reil and Diffuse Periaxial Encephalitis—In Foix and Marie's opinion, sclerosis of the island of Reil and diffuse periaxial encephalitis represent two clinical forms of the same disease The first form is chronic the second is subacute and frequently fatal Observations of two patients, aged 14 and 63, respectively with the chronic form are reported The disease is characterized by a syndrome of spasmodic paralyses, developing within a few days or weeks Sensory disturbances among them reduction of vision may be an initial clinical manifestation Mental derangement consists in apathy and slow ideation This is succeeded by a second phase, in which periods of regression occur The third phase is the phase of sequelae, it starts a year or a year and a half after the beginning of the disease Paralysis of all four limbs, blindness, idiocy and epilepsy were the sequelae in the younger patient Bilateral location of the lesions is an important differential sign from tumor of the brain The disease may also be confounded with optic neuromyelitis The latter can be distinguished by the changes in the cerebrospinal fluid and by the difference in its course In children, sclerosis of the island of Reil should not be mistaken for infantile encephalitis

*Hyperglycemia Induced by Secretin H Hermann —p 381
*Activity of Insulin and Dysfunction of Endocrine Glands G P. Sacharoff and J S Danenkoff —p 416

Hyperglycemia Following Injections of Secretin.—Hermann's researches were made on dogs with a pancreatic fistula Injections of secretin, prepared by the Bayliss-Starling method (the technic is given), were followed immediately by hyperglycemia The average increase of the blood sugar was 25 per cent of the initial glycemia. The hyperglycemia lasted half an hour, it was succeeded by hypoglycemia Further by means of alcohol, secretin was separated from associated hypotensive substances The secretin and these substances were injected separately in another series of animals There was evidence that the primary hyperglycemia is due to the hypotensive products The action of secretin consists in stimulation of the pancreatic secretion it causes the hypoglycemia In seven transfusion experiments, both suprarenals were removed from the recipient dog, then the jugular vein was anastomosed with the suprarenal vein of the donor dog The latter was injected with secretin This resulted in an increase of epinephrine secretion in the recipient dog The origin of hyperglycemia from secretin is thus traced to the organs secreting epinephrine

Paradoxical Action of Insulin and Dysfunction of Endocrine Gland—Sacharoff and Danenkoff's study tended to verify the influence of certain substances on the action of insulin on the blood sugar Fasting rabbits were given an injection of insulin, followed soon by an injection of one of the substances tested Small doses of calcium increased the action of insulin, large doses considerably decreased its action Magnesium constantly reenforced the effect of insulin The action of sodium, potassium and phosphate was analogous to that of calcium Distilled water appeared to enhance the action of insulin The results confirm Kraus' theory that electrolytes play an important role in hormonal activity Diet, fatigue, possibly even the seasons influence the effect of the hormone In addition, changes in ion reactions induced by lesions of an endocrine gland may influence the action of a hormone on the intact gland.

*Local Autohemotherapy in Trachoma A Campoy Ibanez —p 185
*Serology of Leprosy J Bejarano —p 207

Autohemotherapy of Trachoma.—In 157 patients with trachoma, Campoy tried local autohemotherapy (washing the eye with blood from the patient) His statistics show 63 69 per cent unconfirmed cures, 31 84 per cent confirmed cures, 2 54 per cent recent cures, and 1 91 per cent improvement when the patients stopped treatment The method has proved useful in both sexes and at all ages There are no contraindications nor eye reactions Results are obtained more quickly than with any other method Campoy describes in detail his cases, and the method and the devices which have proved most efficient From seven to twelve treatments were given, the time needed for recovery was from sixteen to forty-three days

Serology of Leprosy.—In twenty-two lepers studied by Bejarano, the blood Wassermann reaction was positive in 52 5 per cent, the Hecht reaction in 60 per cent and the Meinicke reaction in 36 per cent The tubercular type gave the largest number of positive reactions, the anesthetic type the largest number of negative reactions The syphilitic antigen proved the most efficient in the tubercular type and the cholesterolized normal in the mixed type The sedimentation speed test has no relation to the serum reactions These change comparatively quickly, in accordance with the florid nature of the disease Treatment alters the reactions, but not as quickly as in syphilis The spinal fluid reaction is regularly negative

Congenital Hydronephrosis in Two Brothers.—The photographs show the types of congenital hydronephrosis in two brothers. One had in addition a thickened ureter. In the other the defect seemed to be due to a slightly spiral ureteral implantation. Pressure exerted on the pelvis did not elicit urine.

Accident Caused by Prostatic Massage.—While Castaño's patient was massaging his own prostatic gland, a vein tore. An enormous hematoma developed. Castaño has not found a similar case in the literature.

Uncommon Complication of Gonorrhea.—Spurr describes the case of a boy, aged 19, who lost the use of his legs and all muscular power two months after contracting gonorrhea. No spontaneous pain existed, but the slightest pressure on the back of the thigh caused severe pain. With treatment aimed at the gonococcus, the patient gradually recovered the use of his legs. The therapeutic response confirmed the diagnosis of sciatic neuritis of gonorrheal origin.

Ascarid Infestation Resembling Meningitis in an Infant.—A girl, 22 months old, was brought to the hospital with meningeal symptoms. From the history, it appeared that worms had been expelled. Lumbar puncture yielded no sign of meningitis. Santonin was used and a large number of ascarids were eliminated, after which the patient improved and the meningeal symptoms subsided. A few days later bronchopneumonia with myocarditis developed, and the child died. At necropsy, the intestine was found filled with ascarids, some of which were present even in the stomach The enormous number is evidence of an old condition, while the recent symptoms had been acute, appearing within the last three days. Instead of supporting the idea that ascarids may cause meningitis, the facts bear witness to the tolerance of the body to these worms.

*Blood Agglutinins in Brazilians. J. Aben-Athar.—p. 145.
The Leprosy Problem. H. C. dé Souza Araujo.—p. 154.

Blood Groups in Brazilians.—In a miscellaneous series of 274 Brazilians, 50 per cent belonged to group 1; 29.5 per cent to group 2; 17.8 per cent to group 3, and 2.5 per cent to group 4. The biochemical index, i. e., the ratio between groups 2 and 3 (B) was 1.6. Among eighty-four white Brazilians, the proportions represented by the different groups were respectively, 42.8, 40.4, 14.2 and 2.3 per cent; among forty-six Portuguese, 34.7, 47.8, 13.0 and 4.3 per cent; among ninety-three half-breeds, 51.6, 31.1, 15.0 and 2.1 per cent; among seventy-two mulattoes, 44.4, 33.3, 19.4 and 2.7 per cent; among sixty-five half-breed Indians, 61.5, 15.3, 21.5 and 1.5 per cent, and among thirty-two negroes, 40.6, 25.0, 28.1 and 6.2 per cent, respectively. The negroes and half-breeds have for some time shown a progressive decrease in Brazil. The Jansky numbering was used in the study.

New Technic for Isolating the Soft Palate in Rhino-Pharyngeal Operations. L. Samengo.—p. 769.
The New Methods of Treating General Paralysis. G. Revault D'Allonnes.—p. 775.
Melancholy Stupor and Its Relation to Parkinson's Disease. J. M. Obarrio.—p. 778.
*Radium Therapy of Cancer of the Eyelid. N. Capizzano.—p. 795.
Abscess of the Liver. G. Segura.—p. 799.
*Leukocyte Count in Rabies. R. Esquivel and C. G. Lasta.—p. 804.
*Treatment of Burns with Brewers' Yeast. A. Cappelletti.—p. 815.
*Insulin in Dermatology. J. J. Darnet.—p. 819.

Radium in Cancer of the Eyelid.—Recently (1924-1926), Capizzano has treated seventy cases of epithelioma of the eyelid with radium exclusively. The cures amount to 74.28 per cent. Recurrences have not been more frequent than with other forms of treatment. The ages of the patients were from 20 to 80 years.

Leukocyte Count in Rabies.—In rabbits inoculated with fixed virus, Esquivel and Lasta found an average increase of neutrophils of 79.77 per cent; the lymphocytes decreased on the average 60.32 per cent in fifteen out of eighteen cases; the changes in the monocytes were inconstant; the eosinophils decreased 100 per cent in thirteen out of eighteen cases and from 10 to 60 per cent in the rest; the mast cells decreased on an average 58.53 per cent in fourteen cases and increased in four.

Yeast in the Treatment of Burns.—Dressings impregnated with brewers' yeast gave excellent results in the treatment of burns in Cappelletti's cases. The method was suggested by Plantier.

Insulin in Skin Diseases.—In all cases of a chronic skin lesion, Darnet advises investigation of the blood sugar. If a high content is found, insulin should be tried. Even when the figures are normal, an induced hyperglycemia test may yield a different result. In more than 100 cases of eczema, furunculosis, psoriasis, arsenical erythroderma, ulcers of the leg, intertrigo and acne, insulin was used and proved curative in many. The dosage was rather high, occasionally as much as 100 units a day.

*Retention of Salts in Infants. E. Rominger and H. Meyer.—p. 195.

Tonsillitis with Lymphatic Reaction. — Koenigsberger observed eighteen cases of acute lymphadenosis in children. The high fever and absence of general depression speak against acute leukemia, the lymphocytosis and absence of albuminuria against diphtheria. In some cases only a retrospective diagnosis can be made—for instance in one of their patients in whom the tonsillitis had apparently provoked an attack of hemorrhagic purpura. The lymphocytosis lasts for several weeks or months.

Ossification of Carpus and Forearm.—Munk measured the size of the centers of ossification in the bones of the carpus and distal end of the radius and ulna in children of various ages between birth and puberty.

Retention of Salts in Infants.—Rominger and Meyer found that the retention of minerals in healthy infants (breast-fed and artificially fed) depends to a large degree on the amount of minerals in the food. Therefore, the artificially fed infant suffers a certain degree of supermineralization, without corresponding retention of water, which, however, does not seem to cause any trouble.

Stuttgart Society for Study of Personality. Basler.—p. 501.

Interfereometric Method.—Streck found that the precautions recommended in making the interfereometric modifications of Abderhalden's test are irrelevant. Furthermore, he saw no difference in the reaction when the serum was incubated with the organ powder for twenty-four hours, as directed, or for one hour or for three days. Room temperature was just as good or bad as the incubator. He attributes the observed concentration of the serum to imbibition of the organ powder by the water of the serum.

Nitrite Test in Urine.—Hirsch confirms the advantages of the Weltmann-Haslinger technic for determination of nitrites in the urine. Fresh urine is mixed with an equal volume of Gries' reagent, consisting of 0.2 Gm. of alphanaphthylamine dissolved in 20 cc. of boiling water and filtered into 150 cc. of diluted acetic acid. This solution is mixed with a solution of 0.5 Gm. of sulphanilic acid in 150 cc. of diluted acetic acid. The mixture is stable in a dark bottle. A red color indicates the presence of nitrites. A negative reaction means either that the urine is sterile, or that it is infected with bacteria which do not form nitrites (gonococci, streptococci or tubercle bacilli). Two further possibilities are that not enough nitrites have been formed or that the urine did not contain enough nitrates. These last two possibilities are checked in the following manner: A two hour incubation at 37 C. gives the bacteria time to produce enough nitrites. Another sample of urine is incubated for one-half hour after the addition of a few drops of a 10 per cent solution of sodium nitrate, and is then tested for nitrites. A positive nitrite reaction in an acid urine makes a colon bacillus infection highly probable. Any positive result is reliable; negative results do not exclude infection.

Measuring Fatigue.—Strauss measured the electric current derived from the upper extremity and from the mucous membrane of the lower lip. He found that fatigue lowers the difference of potential between these two regions (by increasing the potential of the skin). The time required for restitution seems to be fairly constant in the same individual. He hopes to develop this method to an objective measurement of fatigue.

The Blood Under Low Atmospheric Pressure.—Seyfarth observed an increased percentage of erythrocytes with supravital granulations in animals kept at low air pressure. The rapidity of the increase depends on the general condition of the animal. The granular erythrocytes have a larger diameter than the mature cells.

By-Effects of "Synthalin."—Adler noted an increase of urobilinogen in the urine of patients treated with "synthalin." In addition to this, Holzweissig observed a case of jaundice apparently due to this treatment. The gastro-intestinal disturbances following the use of "synthalin" may be prevented by the simultaneous administration of biliary salts—for instance, 0.5 Gm. of sodium dehydrocholate with every dose of "synthalin."

Tumors of the Spinal Cord. K. Singer.—p. 405.
*Influenza and Alcohol. Bornstein.—p. 422.

Action of Iodine on the Circulation.—Guggenheimer and Fisher determined the action of iodides on the isolated heart. At first—with perfusion containing iodine diluted 1:75,000—they noted only a depressing effect on the contractions. With increasingly high dilutions—up to 1:5,000,000—there was besides this a distinct vasodilation, evidenced by increase in the perfusion rate. Further dilutions (1:12,500,000) were inactive. They point out that the normal iodine content of the blood (from 1:8 million to 1:12 million) is just below the lower limit of action of iodides. They had good therapeutic results in angiospastic conditions with the daily administration of from 0.015 to 0.03 Gm. of sodium iodide, divided into from three to six doses. Because of the simultaneous depressive action on the heart, the treatment should be combined with theobromine preparations or supplanted by them, if the heart is failing or in malignant sclerosis of the kidneys with permanent high blood pressure.

Influenza and Alcohol.—Bornstein, secretary of the Association of German Total Abstainer Physicians, points out that the alleged protective action of beer or other forms of alcohol in influenza is not established scientifically, and quotes against it another physician who claimed to have cured 299 soldiers suffering from influenza without the use of alcohol.

"Skull Trauma."—Martin vigorously opposes those pathologists who recently (at the meeting of the Deutsche Gesellschaft für Kinderheilkunde) urged more active measures on the part of obstetricians, in order to avoid injury to the brain and the vessels of the skull of the child from the birth process. Such an injury is rare, and in no wise justifies a departure from conservative practice.

Effect of Insulin on the Specific Dynamic Action of Foods. A. Sachs et al.—p. 175.

Angina Pectoris and Insufficiency of Right Ventricle.—In certain patients with angina pectoris Wassermann found an enlargement of the liver due to insufficiency of the right ventricle. With insufficiency of the left ventricle, the attacks of angina pectoris cease, as a rule.

Functional Dissociation of Respiration.—Condorelli and Rechnitzer studied volitional forced apnea in healthy subjects. In spite of an occlusion of the respiratory passages, unavailing respiratory movements appear after a time and increase until the subject gives up his voluntary apnea. The first movements are frequently limited to the diaphragm without any participation of the auxiliary muscles. The authors also discuss the mechanism of Cheyne-Stokes' respiration.

Pregnancy and Heart Block.—Dressler confirms the fact that complete heart block may not impair the prognosis of pregnancy, if careful examination excludes the possibility of serious myocarditis. On the contrary, partial heart block—even the slightest disturbance of the conduction—may signify extensive involvement of the myocardium and, as a rule, contraindicates pregnancy and especially labor.

Congo Red in Diagnosis of Amyloidosis.—Strasser's experience with this test was good. He observed retrogression of the amyloidosis in a young girl after amputation of the leg for osteomyelitis of the tibia. The associated nephritis, however, was not influenced.

Splenomegalic Lymphogranulomatosis.—Holler and Paschkis report two cases of lymphogranuloma of the spleen. One of the patients had a typical hemolytic jaundice, and the unexpected supplementary diagnosis was made on the extirpated spleen.

*A Case of Gastro-Ileostomy. J. Galpern.—p. 144.
Pseudometeorism Simulating Tuberculous Peritonitis. O. Wiedhopf.—p. 145.

Treatment of Fistulas of Duodenum and Small Intestine.—In a case of duodenal fistula after cholecystectomy, at which drainage of the common bile duct had been established, Volkmann introduced a catheter from the common bile duct into the efferent duodenum, with the object of supplying nourishment and of allowing the fistula to dry. The patient died shortly after, perhaps because the procedure was not thought of till too late. He also recommends that the method originated by McKenna for treating postoperative paralysis of the stomach be tried in duodenal fistula. The jejunum is exposed just beneath the duodenojejunal flexure and secured to the wound with sutures. Two catheters (number 18) are then sutured in, side by side, so that one leads to the stomach, the other to the small intestine.

Treatment of Bleeding Nipple.—Erdheim's standpoint is that a mutilating radical operation, with removal of the axillary glands, is not necessary in all cases of bleeding nipple. The latter is a symptom common to a number of pathologic processes, many of which can be cured by resection. In papilloma of the lactiferous ducts and the so-called precancerous process, the diseased tissue may be excised and the opinion of the pathologist obtained before proceeding further. He holds that the surgeon's aim should be the smallest operation that will produce a cure. Risak states that the standpoint of Hochenegg's clinic is that while operation is always indicated in case of bleeding nipple, a mutilating operation is not justified unless there is clinical or histologic evidence of carcinoma. Klose, replying to Erdheim and Risak, regrets that the discussion has become one of operative methods. There is great need of research by surgeons on the transition stages between benign and malignant growths. If only those lesions which are certainly carcinoma are treated radically, the statistics of recurrence will remain as they are. Improvement can come only from radical operation in precancerous stages. In his experience, bleeding nipple has proved a reliable guide. Atypical epithelial proliferations have been found in every case. A larger material is necessary to a final decision in the question, but, when this decision is arrived at, the question of what operation is best will be answered automatically. Pribram affirms that in a large majority of cases the cause of bleeding nipple is a lesion which he designates as hemorrhagic cystepithelioma. This lesion he describes at length. It is a papilliform epithelioma in a lactiferous duct which has undergone cystic enlargement. It is a localized process, near the nipple. The mammary gland may be entirely unchanged. Bleeding is the rule. The cyst varies in size from a pea to an orange. The overlying skin is usually not freely movable, but retraction of the nipple is rare. Bleeding from the nipple may precede the palpable tumor by many years. The tendency to metastasis is not great, and the axillary glands are nearly always free. The possibility of carcinomatous degeneration undoubtedly exists, and amputation of the breast should be practiced, but the necessity for removing the axillary glands does not appear to exist, if the lesion is, with certainty, a cystepithelioma.

Bladder Sutured to Poupart's Ligament During Herniotomy.—A young woman was confined to bed for eight months after operation on a left (probably inguinal) hernia. Her symptoms, which started the day after the operation, were pain in the bladder, bloody urine and a frequent desire to urinate, associated with pain. A second operation showed that the bladder had been sutured to Poupart's ligament. It was freed and the patient recovered.

Gastro-Ileostomy.—Six months after operation for gastric ulcer, the symptoms returned with increased severity. A second laparotomy revealed that at the first operation the ileum, instead of the jejunum, had been joined to the stomach. A typical peptic ulcer was present in the intestinal wall opposite the anastomosis. The case shows that it is possible to mistake the last loop for the first, and is a warning that one should not rely on the length of the mesentery for guidance, but should work under the control of the eye.

*Bringing Case Reports Up to Date. V. E. Mertens.—p. 204.

Cholascos.—The problem of the acute intoxication and chronic cachexia without jaundice which follow the effusion of large quantities *of bile into the peritoneum was studied* in dogs by Melchior, Rosenthal and Wislicki. They found that ligation of the common bile duct and opening of the gallbladder resulted in the collection of bile acids in the blood and tissues, in such amounts that most of the animals died from bile acid poisoning in from twenty-four to forty-eight hours. *The absence of jaundice is explained by the fact that* the bile pigments, taken up by the blood, are excreted into the abdominal cavity by the liver, in so far as they are not eliminated with the urine. The excretion of bile acids is a slower process. It appears from these experiments that cholemia is misnamed, and that the syndrome thus termed is a *consequence of hepatic insufficiency,* rather than of the presence of bile acids in the blood. In cholascos there is a true cholemia—a direct poisoning by bile acids.

Bringing Case Reports Up to Date.—Mertens suggests that brief reports of progress or of further operations on patients whose cases have already been published should be sent for publication to the central organ of the *specialty concerned.* In this way, the end-results of many interesting cases, now hidden away in hospital archives, would be made available.

Antiseptic and Antitoxic Action of Balsam of Peru in Wounds.—In Brunner and Silberschmidt's experiments, balsam of Peru prevented death in three out of four guinea-pigs in which it was introduced into a cutaneous muscle wound, together with earth containing, in lethal amounts, the microorganisms of malignant edema and tetanus. In the fourth animal, life was prolonged. In the animal that survived, a circumscribed abscess formed, which broke spontaneously. Bacilli of the Fraenkel group and a few tetanus bacilli were found in the pus. The dose of balsam of Peru was from 1 to 1½ cc.; the quantity of earth, 0.05 Gm. In a further series of guinea-pigs, the balsam of Peru was introduced into the wound six hours after the infected earth. Two of these animals survived. When the interval was longer than six hours, the balsam was without effect. The six hour interval corresponds to Friedrich's incubation time. To study the *antitoxic action of the balsam, the authors introduced into* a cutaneous muscle wound in guinea-pigs a lethal dose of tetanus or botulinus toxin, followed immediately by the balsam. All the animals died, although death was postponed as long as five days. A further series of guinea-pigs were treated with subcutaneous injections of balsam and toxin mixed in vitro. All the animals thus treated remained alive. Some of the doses and the intervals between mixture and injection were as follows for guinea-pigs weighing 360 and 320 Gm., respectively: balsam of Peru, 0.2 cc., tetanus toxin, 1/120 cc., interval 5 minutes; balsam of Peru, 0.5 cc., toxin, 1/50 cc., interval two days.

New Forceps for Introducing Gauze. P. Beck.—p. 181.

Intra-Uterine Pressure in Normal Pregnancy and in Hydramnion.—In three cases of hydramnion and in three cases of normal pregnancy (studied as controls) puncture of the uterus was performed from a point in the median line below the umbilicus, and the intra-uterine pressure was determined. After deductions for known sources of error, it appeared that intra-uterine pressure existed neither in normal pregnancy nor in slowly developing hydramnion.

Pregnancy and Labor in Women in the Textile Industry.—This study, made by Hirsch, comprises 3,165 completed pregnancies of women employed in the textile industry. The course of labor was pathologic in 34.4 per cent. Pathologic labors were 18 per cent more frequent in women who worked standing than in those who sat at their work. Premature births, stillbirths, forceps deliveries and cesarean sections were about 50 per cent more frequent in these women than in the general population; they were much more frequent in the women who stood than in those who sat at their work. Varicose veins occurred nearly three times as often in the women who stood as in those who sat.

Treatment of Eclampsia.—Stoeckel analyses the eclampsia cases seen at the Leipzig university women's clinic during the time that he directed it (1922-1926). The cases numbered 119. The total maternal mortality was 8.4 per cent, the corrected mortality 5.8 per cent. The mortality of the children was not quite 9 per cent. None of the babies delivered by cesarean section died. His practice is immediate delivery, followed, if it does not succeed, by venesection and narcosis. He fears that any advocacy of primary conservative treatment will lead to these patients being treated at home by physicians lacking in the skill and experience necessary for the individualization essential in conservative treatment.

*Adhesions of the Cervix After Curettage. B. Bass.—p. 223.
*Paraffin Tamponade. A. Landeker.—p. 225.

Adhesions of the Cervix After Curettage.—In the last eighteen months, Bass has seen twenty cases of cervical adhesions after curettage. The clinical picture is as follows: A month or two after the operation, pains resembling labor pains set in. They gradually cease, but return with each menstrual period. There is amenorrhea. The uterus is in most cases smaller than normal; the corpus is tender. The condition may be mistaken for atrophy of the uterine mucosa or for amenorrhea of ovarian origin. Treatment consists in dilating the cervix with sounds.

Paraffin Tamponade.—Paraffin, heated to about 60 C., is poured into a warmed rubber speculum inserted into the vagina. The speculum is withdrawn slowly as the fluid is poured in; and the paraffin mass spreads over the vaginal walls and portio and, finally, completely fills the vaginal cavity. There is no pain, and pressure is not too great to be borne in comfort. Care must be taken on withdrawal of the speculum not to let the hot paraffin touch the sensitive structures of the introitus When, at the end of one-half hour or of several hours, the block of paraffin is removed, the vaginal walls have undergone hyperemia and are thoroughly warmed through There is often considerable secretion, which is succeeded in a day or two by corresponding drying of the walls Landeker recommends this method in pelvic neuralgia and cramps, in inflammatory diseases of the uterus, parametrium and adnexa and in leukorrhea

Formula for Estimation of the Evacuating Activity of the Stomach —In order to establish the emptying ability of the stomach, the amount of the gastric juice secreted between the time of intake of the test meal and that of withdrawal of the remaining food must be known In his calculation, Punin takes for granted that the difference in the quantity of the gastric juice is considerable in various diseases, but that its acidity is almost always the same From 0 4 to 0 5 per cent of free hydrochloric acid is found constantly in the gastric juice The formula suggested is $\frac{v = p \quad a}{0 5 - d}$ Y indicates the amount of the secreted gastric juice, p, the amount of the food introduced, and a the amount of hydrochloric acid in 100 cc of the juice The quantity of the evacuated food is easily estimated by subtracting the amount of the food removed (d) from the food introduced (p) plus the secreted gastric juice (y) Thus $X = (p + y) - d$ The evacuating ability of the stomach was estimated by this method in 250 cases. In twenty eight, the diagnosis was confirmed at operation.

RELATION OF THE SUPRARENALS TO THE SYMPATHETIC NERVOUS SYSTEM *

R. G. HOSKINS, Ph.D., M.D.
BOSTON

The existence of some sort of relationship between the suprarenals and the sympathetic nervous system was foreshadowed by Addison's and Brown-Séquard's observations seventy-five years ago that disease or destruction of these glands results in a train of symptoms in which circulatory weakness is a prominent feature. This probability was rendered almost a certainty by the work of Oliver and Schäfer and of Cybuski and Szymonowicz some thirty years ago. These observers showed that suprarenal extracts powerfully stimulate the arterioles to contract and the heart to beat more forcefully, results that are likewise brought about by sympathetic stimulation. These observers determined that the potent principle was obtainable from the medulla but not from the cortex of the gland. Elliot, in 1905, rounding out the investigations of Langley and Brodie and Dixon, determined that injections of suprarenal extracts and stimulation of sympathetic nerves give similar results throughout the body. This first half-century's work seemed to have solved rather satisfactorily the problem of the function of the suprarenals, at least so far as the medulla is concerned. Since destruction of the glands leads to circulatory failure and administration of suprarenal extracts brings about marked increase in blood pressure, this pressure, it was assumed, is normally maintained by the constant secretion of epinephrine. This idea was extended to include the whole sympathetic system, which was supposed to be kept in tonus by suprarenal secretion.[1]

Little account was taken at this time of Moore and Purinton's [2] observation that high dilutions of suprarenal extract may lead to a fall in blood pressure. This result was vaguely ascribed to the presence of some extraneous depressor substance in the extract that was more potent in high dilution than the epinephrine itself but was ordinarily masked by the latter.

An obvious check on the tonus theory is to ligate the suprarenal vessels and note the immediate effect on blood pressure. Since epinephrine is notably evanescent in its pressor action, if the sympathetic system were being kept active by its aid a prompt fall of pressure should result. Strehl and Weiss [3] put the matter to a test with rabbits and noted the expected fall of pressure at once. As soon as this was apparent the vessels were released, and the pressure promptly returned to its previous level. They did not take into account, however, the fact that stimulation of sensory nerves, such as might result from fastening the vessel ligatures, often gives a brief fall of pressure.

Young and Lehman,[4] and later Young [5] alone, repeated the experiment, but with the difference that the ligatures were kept in place for a considerable time and the immediate reflex effects of the manipulation ignored. It appeared then that the blood pressure was not significantly affected for a period of hours, a time much longer than that needed for the destruction of any accumulated circulating epinephrine. So strongly entrenched, however, was the tonus theory at this time that these incompatible observations received little consideration. Indeed, the period of conflicting testimony in endocrinology as a whole was then in full flower.

In 1912, I,[6] in collaboration with McClure, began a series of studies directed to a critical test of the tonus theory. A repetition of the suprarenal ligation experiments in dogs confirmed unequivocally the results of Young and Lehman. Blood pressure does not fall for hours after the suprarenal factor has been eliminated. The only apparent way to reconcile this fact with the tonus theory is to assume that the anesthesia had paralyzed the suprarenals themselves before the ligatures were tied. Many studies have shown, however, that the suprarenals, like other glands, are capable of secreting while the subject is anesthetized.

The theory was tested in another way.[7] Epinephrine not only stimulates the circulatory apparatus but also depresses the digestive system. If it were shown that gastro-intestinal depression is elicited at least as easily as circulatory stimulation, a high degree of probability would be established that epinephrine stimulation is not ordinarily a factor at all in maintenance of blood pressure. The physiologic price would be too great. Simultaneous records were taken of intestinal peristalsis and blood pressure in dogs. For periods up to ten minutes it was shown that epinephrine by vein stops peristalsis in dosages that leave blood pressure unaffected. Subsequently it was shown by Durant [8] in my laboratory that the same is true of cats, and that the depression of peristalsis can be maintained in both cats and dogs for periods up to an hour without any rise of blood pressure. In rabbits, however, the thresholds are nearly equal and by careful adjustment of dosage slight pressor effects can be secured without gastro-

intestinal paralysis. Only a few millimeters of pressure can be obtained, however, without checking peristalsis.

Another test was carried out.[9] If the blood pressure is constantly maintained by minimal discharge of epinephrine, any augmentation of the quantity of this drug should further increase the pressure. It was found, however, that with high dilutions epinephrine can be administered without any perceptible effect. As the rate of injection is increased a threshold is passed and the blood pressure goes, not up, but down. It would seem, then, that the suprarenals, if they exert any constant effect by continuous discharge of epinephrine, would function as a depressor mechanism. The experiments were extended by determining the rate of epinephrine discharge in anesthetized dogs, the caval pocket method that was subsequently employed extensively by Stewart and Rogoff and by Kodama being used. Under the conditions of these experiments the rate was found to be about one-fifth that requisite to evoke even the depressor effect of epinephrine. The rate of injection was then increased until a minimal pressor effect was obtained. This occurred only when some twenty times as much of the drug was injected as was being secreted by the suprarenals themselves. On the quantitative side I have never regarded these experiments very highly because of the abnormal conditions under which they were carried out; i. e., under anesthesia immediately after extensive abdominal operations. *That the effect of epinephrine in minimal doses* in normal subjects, however, is often depressing has been reported by various subsequent observers.

The results of the foregoing experiments seemed to render the tonus theory untenable. Nevertheless, the *stubborn facts remained that destruction of the suprarenals* kills the subjects, and low blood pressure is an outstanding feature of the terminal symptoms. *Elliott*[10] *had offered the suggestion and supported it* by an observation on a moribund cat that epinephrine acts to keep up blood pressure, not as an immediate stimulant, but as a factor in maintaining the functional integrity of the sympathetic mechanisms. This possibility, too, was put to test.[11] Granting that moribund animals are moribund and hence not susceptible to stimulation, it seemed logical to investigate the condition of the sympathetic system as the animals began to show well marked symptoms of suprarenal failure but while still able to react. It was found, in brief, that such animals respond perfectly well to stimulation of the vasomotor mechanism either electrically or by drugs, such as nicotine or epinephrine, at a time when muscular and cardiac weakness are strongly in evidence.

In acute experiments, then, the low blood pressure is to be ascribed to cardiac weakness rather than vasomotor failure. Indeed, the maintenance of normal blood pressure for a considerable period after cardiac failure begins to be apparent indicates that there is a compensatory overfunction of the vasomotor system. The problem was investigated further on eleven dogs deprived of from one half to seven tenths of their suprarenal tissue.[12] Blood pressure as well as the reactions to nicotine and epinephrine were determined aseptically before the operation and then at intervals of from one to eight days later. It was found that the reaction to nicotine, and hence the irritability of the sympathetic ganglions or centers, was materially depressed but that the reaction to epinephrine remained as before the operation. That part of the sympathetic system, the terminal "receptive substance," on which epinephrine exerts most of its stimulating effect was therefore not affected. The observations were interpreted as [illegible] central depression was only a phase [illegible] interference with fundamental metabolism characteristic of suprarenal deficiency. Since this depression always ensues when the cortical tissue of the suprarenals is destroyed but not at all when the epinephrine-containing medulla is removed, it is probable that it was not a question here of any epinephrine effect at all.

In connection with the last mentioned experiments, the effect of slowly infusing epinephrine into the blood stream of two suprarenalectomized dogs was tried. To our surprise the sympathetic irritability, as indicated by the reaction to nicotine, was not only not increased but was materially decreased. *The experiment was then* extended to include forty-four dogs, some with partial or complete removal of the suprarenals and some without interference with these glands.[13] In no instance was satisfactory evidence secured that epinephrine in any dosage increased sympathetic irritability. The sympathetic system was stimulated reflexly by means of the faradic current applied to sensory nerves and directly by faradizing the splanchnic nerves or by injecting nicotine. In numerous cases during the administration of epinephrine, the reaction to moderate stimulation was almost or completely abolished. Care was taken that the epinephrine should not be administered in amounts to raise the blood pressure to a point that would, in itself, prevent or mask the effects of the stimuli applied. Also, *the epinephrine depression* was found to be as well marked when the blood pressure was kept from rising by the administration of amyl nitrite.

A considerable amount of cogitation has been devoted to an attempt to formulate a theory of suprarenal function that would comfortably include the foregoing data. So far as they alone are concerned, it might be assumed that the primary function of the glands is, as many students of the problem have thought, to serve as a detoxicating mechanism. The "toxin" might be epinephrine itself or some allied chemical body that is picked up by the suprarenals and converted to an inert form for ultimate excretion, much as ammonium compounds of the body are converted to urea. The stored epinephrine might then, as a secondary adaptation, be discharged under emergency conditions and aid in integrating the body for muscular activity.

It would have to be assumed that the peripheral stimulating effect of the epinephrine itself would so surpass its depressing effect on the sympathetic system proper as to render this negligible. On teleological grounds, the intrinsic ineptitude of such an arrangement would render the theory far from attractive. Moreover, Cannon and Britton[14] have recently published evidence that even so slight a stimulus as walking across the floor suffices to call out epinephrine secretion in amounts sufficient to stimulate the denervated heart. It must be remembered in this connection, however, that severing sympathetic nerves results in augmenting the irritability of the terminal mechanism. However difficult to accommodate, the data to the effect that epinephrine in the blood stream does depress sympathetic irritability remains, so far as I am aware, uncontroverted. On the whole, then, in the present state of our knowledge, perhaps the most plausible assumption is that epinephrine consistently and generally exerts a biphasic effect as it has been shown to do in cases of intestinal peristalsis, uterine contractions and blood vessels in muscles. In that case it would serve under ordinary conditions, if present at all, as a sympathetic sedative, as does calcium, another normal constituent of the blood. Under other conditions its stimulating effect would come into play. The apparent paradox is at first thought not attractive. But it is no more unattractive, perhaps, than a similar paradox to which all have become reconciled; namely, that peripheral stimulation of a sensory nerve may result in either fall or rise of arterial pressure, depending on various accompanying conditions, but especially on the amount of stimulus applied. Indeed, this conception of the action of epinephrine will be recognized as conforming precisely to Verworn's theory that inhibition, in general, is due to subminimal stimulation.

RATIONAL BROMIDE TREATMENT

NEW METHODS FOR ITS CONTROL *

OTTO WUTH, M.D.
Associate in Psychiatry, Henry Phipps Psychiatric Clinic,
Johns Hopkins Hospital
BALTIMORE

Bromide treatment to be rational must, on the one hand, produce the desired effect of the drug and, on the other hand, avoid the danger of bromide intoxication. The foundations of bromide action, and consequently also those of a rational treatment, are based on the relations between chlorides and bromides—the chloride-bromide equilibrium or replacement—which therefore has to be discussed briefly.

Sodium chloride constitutes the greater part of the electrolytes of the body, and its ions are essential for the function of most cells. Since it is constantly excreted, mainly in the urine, it must be constantly replenished. The body maintains its chloride concentration with remarkable constancy. The excretion varies with the salt intake but lags somewhat behind in time. According to Borelli and Girardi,[1] with a steady income, equilibrium is reached within three or four days. If the supply of salt is stopped, excretion falls within three days to a lower level, but the body retains its normal salt content.

The excretion of chlorides can be hastened by the administration of bromides and iodides.[2] Conversely, the administration of chlorides hastens the elimination of these salts.[3]

If bromides are introduced into the body their excretion starts rapidly but proceeds very slowly;[4] so slowly, in fact, that even twenty days after medication has been stopped the excretion of bromides is not completed.[5] Hence, a retention of bromides takes place[6] which is due to the fact mentioned that bromides in part replace chlorides. Thus, a sort of constant "saturation" of the body with bromides takes place, so that after a certain period in prolonged medication no more bromides are retained, and intake and excretion are balanced.[7] The chloride content of the blood is then diminished, the chlorides having been partly replaced by bromides.

A replacement of more than 40 per cent of the chlorides of the blood by bromides, according to Bernoulli,[8] is fatal. Intoxication symptoms generally appear, according to the experiences of Ulrich[9] gained by examination of the urine, when from about 25 to 30 per cent of the total halogens are represented by bromides; there exist, however, individual differences, a fact that must be borne in mind.

After this, it is easily understood that the action of the bromide medication depends not only on the bromide intake but also on the chloride intake. That is to say, prescribing bromides without knowing the chloride intake or the bromide saturation is the same as letting a patient take as much or as little bromides as he chooses. The relations are clearly demonstrated in chart 1, which was constructed from Bernoulli's figures. Abscissa and ordinates of the chart give the intake of sodium chloride and sodium bromide; the curves give the urine saturation level. The fact is emphasized by Ulrich, that with equal doses of chlorides and bromides, bromide intoxication is produced in three weeks.

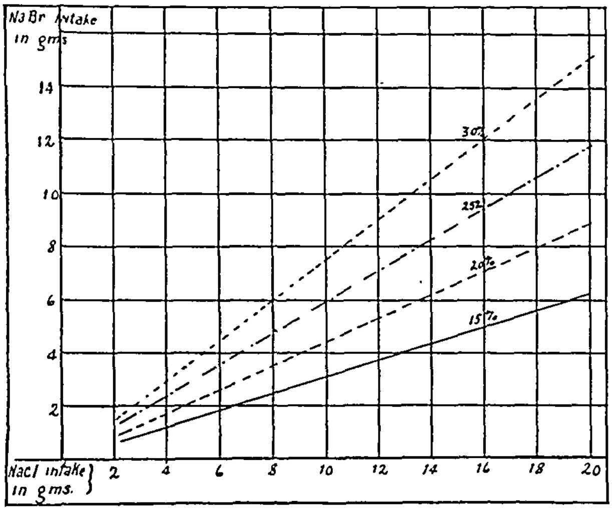

Chart 1.—Graphic illustration (from figures of Bernoulli) that the maintenance of a certain level of urine bromides to total urine halogens is dependent on the variation in sodium chloride intake as well as bromide intake.

The methods for determining bromides in the blood or urine, i. e., in the presence of chlorides, are somewhat tedious and require a chemical laboratory outfit as well as some technical skill.

Walter[10] described a color reaction between gold chloride and bromides; his colorimetric method, however, according to Bieling and Weichbrodt, is practically useless, the limits of error are so great. Hauptmann's[11] modification gives better results but requires a colorimeter.

I aimed to develop a method which would be simple enough for practical use and not require special equipment, and therefore devised a comparator consisting of tubes containing certain dyestuffs, the color shades of which correspond to the color changes of certain bromide concentrations after the addition of gold chloride.

The principles of the method involve the coagulation of the serum and the addition of gold chloride to the filtrate, producing color changes corresponding to the bromide concentration and varying from a yellow greenish brown to a red brown. The reaction is specific for bromides with the exception of the iodides. Naturally, the coagulate retains some bromide; the retained amount varies slightly with the different protein content of different serums and mainly with the absolute bromide content; this causes a definite but, as will be seen, a negligible, error, in the clinical results. Table 1 shows the errors of different concentrations and with *different serums. It is easily seen that the error* increases with the concentration of bromides. As the comparator, however, does not regard differences lower than 25 mg. per hundred cubic centimeters in the weaker concentrations, and in the higher concentrations only differentiates between 200 and 300 mg. per hundred cubic centimeters, the error of the method can be neglected. After all, I do not intend to make a quantitative chemical determination but rather an estimation which serves adequately for practical clinical use.

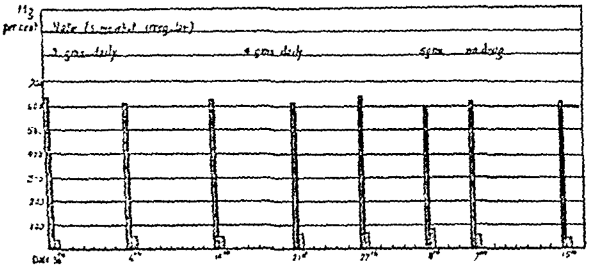

Chart 2 (case 1).—Admission, Sept. 19, 1925.

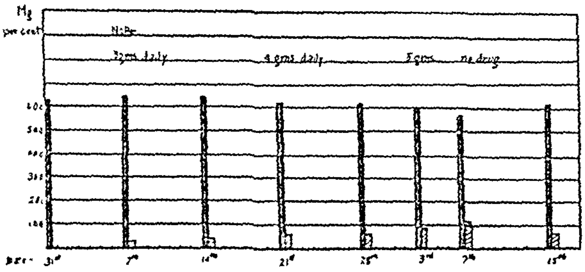

Chart 3 (case 2).—Admission, March 13, 1926.

Therefore, from this standpoint, it seems better to have an approximately exact *method rather than none at* all, and that the method meets this demand can be seen from the cases to be described later.

TECHNIC

The method of procedure is as follows: Ten cubic centimeters of blood is drawn from a vein of the patient and allowed to coagulate. To 2 cc. of serum, 4 cc. of distilled water and 1.2 cc. of 20 per cent trichloracetic acid are added. After standing for half an hour, the mixture is filtered through a small filter. The filtrate must be clear; if necessary, the solution is refiltered. To each cubic centimeter of filtrate, 0.2 cc. of 0.5 per cent gold chloride (Merck) solution is added, and then compared in the comparator with the color tubes. On the color tubes are figures which indicate the milligrams of sodium bromide per hundred cubic centimeters of serum.[12]

Table 1.—*Errors with Different Concentrations and Different Serums*

Bromides Added to Serum, Mg. for 100 Cc.	Bromides Found in Filtrate by Comparator, Mg. per 100 Cc.	Error in Mg.	Error in Percentage
25	24.62, 24.75, 25.0	−0.38, −0.25, ±0	1.5, 1.0, 0
50	46.0, 46.0	−4.0, −4.0	8.0, 8.0
75	64.52, 67.45, 67.65	−10.48, −7.55, −7.35	13.9, 10.1, 9.8
100	91.85, 93.23, 98.0	−8.15, −6.77, −2.00	8.2, 6.8, 2.0
150	130.3, 130.7, 134.0, 132.3	−19.7, −19.3, −16.0, −17.7	13.1, 12.9, 10.7, 11.1
200	177.5, 175.9, 172.6	−22.5, −24.1, −27.4	11.3, 12.0, 13.7

Having described the mode of action of the bromides in its relation to the chlorides, and the method and apparatus for approximate bromide determination, I will demonstrate the practical application of the method in a series of cases.

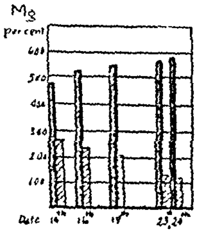

Chart 4 (case 3).—Admission, April 13, 1926

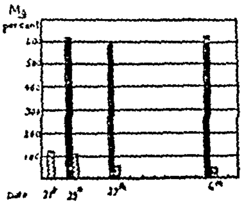

Chart 5 (case 4).—Admission, April 16, 1926.

REPORT OF CASES

Cases[13] 1 and 2.—Varying doses of sodium bromide were given. The charts (2 and 3) were constructed by determining the total halogen amount of the serum by titration with silver nitrate; the bromides were then determined in the serum with the colorimetric method; the chlorides then could be calculated. The black bars represent the chlorides expressed in milligrams of sodium chloride per hundred cubic centimeters of serum. The shaded areas represent the bromides as sodium bromides per hundred cubic centimeters of serum. Both charts demonstrate how the bromides increase slowly with the increased doses of sodium bromides; they also show how the chlorides are diminished as the bromides increase, and finally how bromides are retained in the blood for quite a length of time after bromide administration has been stopped. The results obtained by this simple method check well with the previous results of those authors who have worked with more exact quantitative methods.

Of greater interest are the observations in pathologic cases.

Case 3.—A woman, aged 23, of the schizophrenic reaction type, having taken bromides in large doses, amount *not* known, before coming to the hospital, was admitted, April 13,

---

[12] The comparator with the necessary agents and pipets is manufactured by the La Motte Chemical Products Company, McCormick Building, Baltimore.

[13] In the cases reported, all determinations were made with the colorimeter, with which the percentage of error due to serum absorption of the bromides varies from 0 to —13 per cent. The comparator does not aim to estimate closer than 25 mg. per hundred *cubic centimeters of serum.* Therefore the absorption error can be disregarded, as the comparator allows for variations from 33 per cent in the lower to 12.5 per cent in the higher concentrations. The absorption error therefore always falls within the limits of error of the comparator. Each comparator has been checked against standards with the colorimeter.

1926, with hallucinations, and very severe acne, but without neurologic disturbances.

This was a case of bromide intoxication, the blood containing 264.2 mg. of sodium bromide per hundred cubic centimeters of serum. The acne cleared up rapidly when bromide administration was stopped and sodium chloride solution was given by mouth. The antagonistic displacing behavior of the chlorides stands out plainly.

CASE 4.—A woman, aged 58, had been treated with bromides for some time, doses not known, until suddenly she fell into coma. The disturbance manifested itself in disorientation; drowsy, tearful hallucinations; limitation of the conjugate movements of the eyes; limited, somewhat masklike facial movements; difficulty in swallowing, and regurgitation through the nose; a speech defect suggesting the bulbar type; tremor of the arms; rigidity of the arms and legs to passive movements; hyperactive reflexes; absence of abdominal reflexes, and unstable gait. Because of these symptoms, the case was previously diagnosed as questionable encephalitis, cerebral arteriosclerosis, or pseudobulbar palsy.

When the patient was admitted, April 16, 1926, she had been for some time without bromides, so that the serum bromide content which, April 21, was still 124.4 mg. per hundred cubic centimeters of serum, must have been considerably higher before this date, and in the toxic zone. The condition cleared up rapidly after the administration of salt solution.

CASE 5.—A woman, aged 45, had been taking bromides at home for "nervousness," doses unknown, since the spring of 1925. She developed acute delirium, June 26, 1926, and when admitted, June 28, showed restlessness, disorientation, misinterpretations, visual hallucinations, tremor of the tongue and hands slurred speech, ataxic, reeling gait, and acne. The sodium bromide content of the serum was 339 mg. per hundred cubic centimeters. Treatment with about 150 grains of sodium chloride (10 Gm.) daily in water caused the ataxia to subside in five days; in ten days the speech was clear, and hallucinations were less vivid, and the sixteenth and seventeenth days were free of hallucinations for many hours. The twenty-third day the patient emerged from the delirium, oriented, and with full insight.

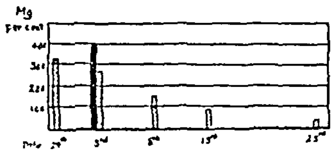

Chart 6 (case 5).—Admission, June 28, 1926.

This was a case of pronounced bromide intoxication with mental and neurologic symptoms. The chart demonstrates that it is sufficient to determine the absolute amount of bromides in the blood without chloride estimation.

CASE 6.—A man, aged 52, who had taken 80 grains (3.2 Gm.) of sodium bromide a day, from May 14, 1926, until May 29, 1926, became sleepy and drowsy, May 29. He was admitted to the hospital June 2, disoriented, delirious and talkative, with visual hallucinations and confabulations. There were thick speech, tremor of the tongue and fingers, absence of abdominal and cremasteric reflexes, and hypalgesia of skin. With chloride administration, the patient recovered completely in eighteen days.

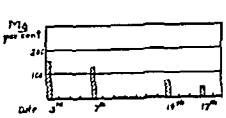

Chart 7 (case 6).—Admission, June 3, 1926.

This patient also represented a case of severe bromide intoxication with delirium and neurologic symptoms, which yielded promptly to bromide elimination.

CASE 7.—A woman, aged 53, had had hypertension with headaches for twenty years. She had taken bromides for five years, amount not known. Now and then morphine had been taken, but the habit had not been formed; the last dose had been taken in February, 1926. There had been five confusional periods with hallucinations since November, 1925. When admitted, May 1, 1926, the patient was approximately oriented. She had visual and auditory hallucinations, tremor of the tongue and underactive knee jerks. Ankle jerks and abdominal reflexes were absent. No medication was given at first; later, salt solution was administered. The visual hallucinations stopped first; then orientation returned. After sixteen days there were free intervals; on the twenty-eighth day the patient was free of mental symptoms and had good insight. She was discharged, May 30, 1926.

As this was one of our early cases, the blood was not tested for bromides until fourteen days after admission. The bromide content was then still 111.3 mg. per hundred cubic centimeters after fourteen days of bromide abstinence. The level on admission must therefore have been considerably higher.

CASE 8.—A woman, aged 61, had suffered from sleeplessness since October, 1926. She took approximately 90 grains (5.8 Gm.) of bromides from the end of October, 1926, to November 15. When admitted to the hospital, November 17, she was delusional, disoriented, and subject to misinterpretations; she had thick speech, difficulty in walking, muscular incoordination, blood pressure from 160 to 190, and albumin, + +, in the urine. The patient developed bronchopneumonia and died, November 27. The bromide content, November 18 (nine days before death), was 207 mg. per hundred cubic centimeters of serum.

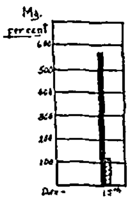

Chart 8 (Case 7). — Two weeks after admission.

This case is one of a bromide intoxication in a patient with cardiovascular disorder. It is of interest that the patient went through a confusional state with speech difficulty in July, 1926, which cleared up entirely with cessation of bromides.

CASE 9.—A man, aged 50, had had difficulty in sleeping since June, 1926. He took 45 grains (3 Gm.) of bromides a day from August 17 to September 17. Then he became delirious, and was admitted, Sept. 20, 1926. He was disoriented, with hallucinations, poor insight and memory, and restlessness. The pupils were irregular, and reacted sluggishly; the tongue protruded to the left with tremor. There was tremor of the lips and fingers; the Romberg sign was positive, the speech slurred, and the writing poor. The blood and spinal fluid (0.4 cc.) Wassermann reactions were positive; 14 cells; Pandy, + + + +; mastic and gold curve, negative. September 28, the patient exhibited his first period of clearness; October 3, he became clear; October 6, there was a flareup of fear and hallucinations, which occurred also on October 11, 18 and 22. He was discharged, October 25, with no personality deterioration, normal memory and judgment. The speech was slightly slurred. The pupils were normal and the neurologic examination was negative.

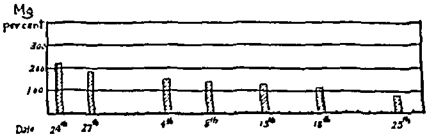

Chart 9 (case 9).—Admission, Sept. 20, 1926.

This case represents a bromide delirium in a case of cerebrospinal syphilis. Without the bromide determination, we would not have recognized that there was a superimposed bromide intoxication and might have thought that the clinical picture was merely due to metasyphilitic disturbances.

CASE 10.—A woman, aged 51, feeling "run down," began, June 17, to take about 100 grains (7.5 Gm.) of bromides a day. She became weak and forgetful; August 5, she was forced to go to bed, because of delusions. August 13, the condition became worse, with disorientation, delusions, and thick speech. When admitted, Aug. 17, 1926, the patient was disoriented, with confabulations, delusions, auditory hallucinations and no insight; test phrases were badly slurred, and abdominal reflexes were absent. August 23, the hallucinations and delusions persisted, although sometimes the patient was oriented. Salt was given by mouth. September 13, the patient was still disoriented to a large extent, with delusions and hallucinations. September 16, she felt better. During the next eight days she was only once delirious during the night;

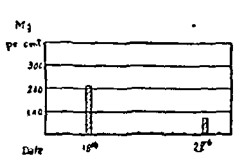

Chart 10 (case 10).—Admission, Aug. 17, 1926.

there was growing insight. October 6, the mental condition was quite clear.

This was a case of bromide intoxication which presented mental symptoms of a delirium.

COMMENT

The series of cases shows how the clinical picture of bromide intoxication varies. The only sign may be a very severe acne; in other cases neurologic symptoms may occur which, together with euphoria, dulness and defective memory, suggest the clinical picture of a general paralysis; again, other cases show delirious states and some finally show an admixture of the bromide intoxication symptoms with the symptoms of the more fundamental disease or reaction type.

It is not my intention, however, to enter on the clinical aspects of the bromide intoxication. I wish only to draw attention to two facts. The first is the frequency of bromide intoxications, which still seems to be somewhat underestimated and is demonstrated by the fact that I was able in six months in 238 admissions to find fifty patients who had bromides in their blood and twenty who showed signs of bromide intoxication—a total of about 21 per cent of admitted patients who had been treated previously with bromides. The second point is that in most of these cases intoxication probably could have been avoided. This is seemingly contradicted by the fact that, in some cases, the doses that were taken were by no means abnormally high. But this contradiction is only apparent. An intoxication can doubtless be produced with the small customary doses of sodium bromide because the chloride intake may be too low; i. e., in an individual case the "normal" dosage of bromides is too high in relation to the patient's chloride balance. That this was the case in most of my patients can be seen by the high absolute bromide content of the serum. It has been demonstrated that equal doses of chlorides and bromides lead with certainty to an intoxication in about seventeen days to three weeks.[14] The routine dosage of bromides (from 45 to 75 grains [3 to 5 Gm.] a day) is based on the chloride intake of about 15 Gm. (225 grains) a day. But not all persons have a chloride intake of 15 Gm. Table 2, which shows the urinary chloride excretion and consequently also the intake, taken from patients who had no other disease leading to a disturbance of chloride metabolism, such as pneumonia, cancer or nephritis, and who were on the relatively uniform hospital diet, demonstrates the enormous individual variations in chloride excretion and therefore intake. Taking into account the interaction of bromides and chlorides, it is evident that if these individual variations of chloride intake are not considered it is merely a matter of luck whether bromide treatment is successful or not, or whether it does or does not lead to intoxication. These facts justify a demand for a clinical method for bromide estimation, and the use of the method for patients under bromide therapy.

TABLE 2—*Urinary Chloride Excretion and Intake*

G.	1,665	5.04

The ideal control would be to determine both the chloride and the bromide content of urine and blood. That, however, will be an impossible task for a practitioner and a very difficult one for institutions, such as state hospitals, which have to deal with a large number of patients under bromide treatment. Therefore, I have tried to present some simpler methods.

URINE TEST IN BROMIDE INTOXICATION

For the chemical diagnosis in a questionable case of bromide intoxication, it will be advisable first to try a simple test for bromides in the urine. If this is negative bromide intoxication can be excluded. This method is as follows:

To 25 cc. of urine about 1 Gm. of animal charcoal is added, mixed well, allowed to stand for a few minutes, and then filtered. To exactly 5 cc. of filtrate measured into a test tube, 1 cc. of 20 per cent trichloracetic acid and 1 cc. of 0.5 per cent gold chloride solution is added; a brown shade indicates the presence of bromides. In order to be able to recognize the color change more easily, it may be advisable for those not yet acquainted with the reaction to prepare the following bromide solution and to treat as follows: To 0.5 cc. of 0.1 per cent sodium bromide solution, 4.5 cc. of water, 1 cc. of 20 per cent trichloracetic acid and 1 cc. of 0.5 per cent gold chloride solution are added. (It must be borne in mind that the presence of iodides will be indicated by a precipitation, whereas in the absence of iodides no precipitation appears.)

If this test is positive, then it will be necessary and essential to determine the absolute bromide content of the serum with the comparator.

For the control of any prolonged bromide treatment it would, of course, be of value if possible to determine the patient's chloride balance in the urine before starting treatment. This control of the urine chlorides could prevent overdosing the patient from the onset. The salt intake, doubtless to a large extent, is determined by individual habit, and the estimation of the chlorides in the urine would inform one, for instance, whether the patient is taking 5 or 10 Gm. daily. In the former case, the bromides may not be prescribed in higher doses than 2 Gm. (30 grains) a day, as a patient otherwise would doubtless develop an intoxication within about twenty days; on the other hand, with a salt intake of 10 Gm. or more, the dose of 30 grains of bromides a day would probably be insufficient.

However, whether this preliminary chloride determination can be made or not, I should like to lay the main stress on the importance of determining the absolute bromide content of the serum. The importance of such a control for the prevention of bromide intoxication has been illustrated by the cases reported.

BROMIDE TREATMENT IN EPILEPSY

Finally, I will add a few words about the bromide treatment of epilepsy.

Ulrich was the first to control the bromide saturation or relative bromide content of his epileptic patients; that is to say, the percentage of total halogens in the urine represented by bromides. He found large individual differences as to the optimal individual saturation. Of forty-eight epileptic patients who had been kept free of convulsions for several years by bromide therapy, ten showed a relative bromide content of from 1 to 5 per cent; nineteen, from 5 to 10 per cent; five, from 10 to 15 per cent; eight, from 15 to 20 per cent, and six, from 20 to 25 per cent. Ulrich's results probably are the best ever obtained by bromide treatment; a status epilepticus has not occurred with his house patients, numbering from 300 to 400, since 1911. These results can be obtained only by a chemical study and control of the patient's urinary or blood bromides. That this method has not been taken up as readily as one would have expected, and as would have been justified, is due to the complexity and methodological difficulties of the Berglunds method, even in Bernoulli's modification, which is used by Ulrich. I hope I have eliminated this difficulty to a great extent by having given a relatively simple technic.

Although my work, to date, with this simplified technic has not been extensive (fifty cases), I feel justified in setting rough standards as to the safety limits of bromide content in the blood serum. I feel that it is not wise to exceed a limit of 125 mg. of sodium bromide per hundred cubic centimeters of serum for the average patient. It seems likely that the bromide tolerance of patients suffering from anemia, malnutrition, cardiorenal disease, and possibly also alcoholism and drug addiction, is lower, and therefore this arbitrary standard may be a little high in these particular cases. On the other hand, in some epileptic patients it is well known that certain factors tend to increase the frequency of convulsions (such as menstruation, unavoidable periods of overwork and excitements, or dietary alterations of salt balance), and under these circumstances it will probably be wise to allow this level of blood bromides to be exceeded. When the blood bromides increase beyond 150 mg. per hundred cubic centimeters of serum, I believe that the patient is liable to intoxication symptoms and therefore speak of bromide content above this figure as the "toxic zone."

As a matter of practical handling of epileptic patients, I recommend the following: It is wise to keep the patient slightly above the lowest level at which his convulsions have disappeared. This slightly increased level will guard against the effect of any sudden increase in salt intake. This will eliminate the possibility of the development of status epilepticus—an ever present serious danger for the epileptic patient. I feel that if convulsions, in the more severe cases, cannot be controlled by bromides up to from 170 to 200 mg. per hundred cubic centimeters of serum, there is no use to attempt to push bromide therapy—in fact, I should advise against maintaining this level for any length of time.

SUMMARY

There are two simplified methods for determining the extent of bromide intoxication: (1) a qualitative test for bromides in the urine, and (2) a comparator method for the clinical estimation of the bromide content of the blood serum.

The qualitative urine test is useful in (*a*) cases suspected of being bromide intoxications, and (*b*) puzzling delirious and organic neurologic cases, which not infrequently prove to be due to bromide intoxication.

In fact, with the simplicity of the method it deserves to be made a routine urine examination. With the frequency of bromide intoxications, it will well repay the little amount of work it requires.

The control of the bromide content in the serum seems essential when bromides are being used either as a sedative or in the bromide treatment of epilepsy.

The chemical control may help to prevent the mistaking of bromide intoxication for organic brain disease (organic deliriums, epileptic psychosis, general paralysis) in epileptic patients who have been uncontrollably dosed with bromides for a long period of time.

In both cases, whether bromides are used as a sedative or as an antiepileptic, the physician will be enabled by the chemical control to have a clear record of the case and also to be safeguarded against self-prescribed changes on the part of the patient. He will be able to avoid insufficient doses on the one hand and intoxication on the other hand, and thus be in a position to render a bromide treatment more rational and consequently more successful.

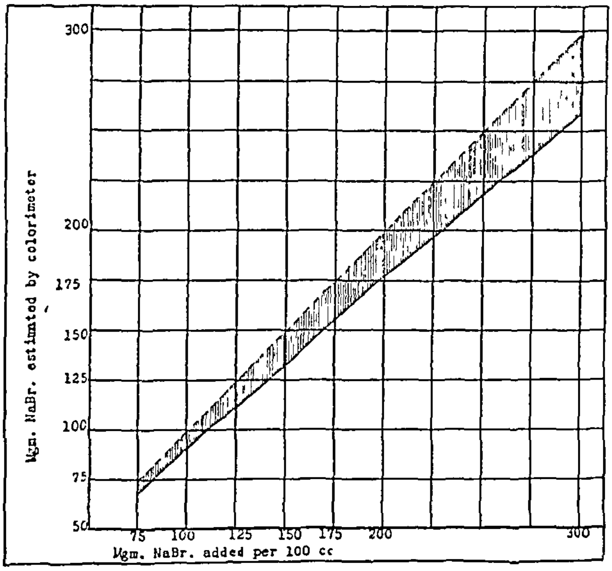

Chart 11.—Shaded area represents error which has been eliminated by standardizing the color tubes in the comparator, accordingly; broken line, sodium bromide in water compared with water standard; solid line, sodium bromide in serum compared with water standard.

A CORRECTION OF COMPARATOR STANDARD TO ELIMINATE ERROR OF SERUM ADSORPTION

Our previous experiments showed that serum adsorbed a certain amount of bromides—this amount increasing proportionally to the concentration of the bromides, and that the amount adsorbed is practically independent of the particular blood serum (between 1 and 4.1 per cent). This adsorption loss is indicated in chart 11 by the shaded portion, which represents the difference in the amount of bromides estimated from watery solution and from serum solutions of known quantities of bromides. The standard solutions in the comparator are corrected to eliminate this error.

THE RATIONALE OF TESTS OF RENAL FUNCTION *

ARTHUR M. FISHBERG, M.D.
Adjunct Attending Physician, Mount Sinai and Montefiore Hospitals
NEW YORK

It did not escape clinicians[1] of a century ago that when a patient with severe renal disease ingests asparagus, turpentine or other substances which impart a characteristic odor to the urine of healthy people, this odor does not appear in the urine. These keen observations were really tests of renal function, in many ways superior to some of the complicated tests that have since been introduced. In this paper I desire to point out that elaborate procedures are unnecessary for clinical purposes, the same end being attained by very simple methods, provided the clinical features of the case are always kept in the foreground. It will first be necessary to consider certain aspects of the pathologic physiology of the kidneys.

THE UNITARY NATURE OF IMPAIRMENT OF RENAL FUNCTION

It is widely held that disease of the kidney may injure the ability of the organ to excrete individual substances, while the excretion of other substances remains unimpaired. But I[2] have pointed out in a previous communication that there is no substantial basis for this view of isolated injury to individual renal functions in diffuse renal disease; available evidence points to there being but one variety of functional injury in renal disease, namely, that involving all the excretory functions of the kidney. In those cases in which there is seemingly circumscribed injury to the ability of the kidney to excrete some individual substance, the cause of the retention of this substance in the organism is not the kidney but some extrarenal factor which results in diminished supply of the substance to the kidney. This universal involvement of all the excretory functions is characteristic of renal functional impairment not only when it occurs in diffuse renal disease but also in such conditions as tuberculous or other purulent disease, polycystic degeneration, or injury to the kidney as a result of stasis following on urinary obstruction.

If any of these variegated anatomic substrata produce impairment of renal function, it is always manifested in the same way, namely, by a diminution in the concentrating power of the kidney for each of the individual urinary constituents. Not one of such substances as urea, uric acid, creatinine or sodium, potassium, calcium, chloride, sulphate, phosphate, indican or urinary pigment can be eliminated in so high a concentration as the normal kidney is capable of attaining. As a result, the total molecular concentration of the urine cannot be raised as high by the functionally impaired kidney as by the healthy organ. As injury to renal function progresses, the maximum concentration which the kidney can attain falls correspondingly, until finally it is unable to elaborate urine of molecular concentration greater than that of the blood.

The excretion of water is impaired along with that of the dissolved urinary constituents. But the kidney's factor of safety for water is very great, and in slowly progressive renal failure this impairment of water excretion is usually masked by polyuria in the effort to compensate for the decreased concentrating power. The actual existence of impaired water excretion can be readily demonstrated in most polyuric patients with markedly decreased concentrating power. If such a patient drinks 1,200 cc. of water within half an hour, he will not excrete practically all within four hours, as does the normal person, but much less, often far under a half. If he can excrete only 400 cc. in the four hours, it is still possible for him to maintain a polyuria, for this amounts to 2,400 cc. in twenty-four hours. As impairment of water excretion progresses, because of renal or extrarenal causes, the patient becomes unable to form a very dilute urine. As a result, the minimum concentration of the urine which the patient can reach gradually rises. But before this, as has been seen, the maximum concentration of the urine has fallen to approximately that of the blood, so the final result is that the molecular concentration of the urine becomes fixed at a level close to that of the blood.

The dilemma of such a patient is obvious. The healthy person can raise urinary excretion by increasing either volume or concentration. But the patient with severely impaired renal function can no longer raise the concentration, so he is dependent solely on raising the volume. And if water excretion becomes progressively less because of advance of the renal process, cardiac failure or a febrile complication, he may no longer be able to raise the volume sufficiently to prevent retention of urinary constituents and consequent uremia.

We do not need complicated laboratory methods to follow these changes in the molecular concentration of the urine and with them the progress of the case. The specific gravity of the urine serves as a measure of the molecular concentration sufficiently accurate for clinical purposes. While it is true, as Addis and Foster[3] have pointed out, that because of the fact that the individual urinary constituents influence the specific gravity to different extents, the less concentrated urine may have the higher specific gravity, it would be rare for this factor to influence the results notably, and it has been demonstrated that the concentration of all the urinary constituents is affected by functional injury to the kidney. When the urine becomes approximately of the same molecular concentration as the blood, its specific gravity is about 1.010, and a figure very close to this is the highest that can be attained by a patient with very severe impairment of renal function. As water excretion becomes more and more impaired, the minimum also approaches this figure. Such a patient may for months have a specific gravity close to 1.010, say between 1.008 and 1.012.

RENAL COMPENSATION AND DECOMPENSATION

Despite the fact that the concentrating power is diminished, the kidney may carry out excretion completely by means of polyuria. According to Albarran's table, at a specific gravity of 1.020 there is usually a urinary volume of 1,350 cc. The same quantity of catabolites can, however, be eliminated by 2,700 cc. of urine of specific gravity 1.010. In analogy to the terms used for diseases of the heart, a patient who, despite impaired concentrating power, excretes completely by means of polyuria, may be said to have a compensated impairment of renal function. Such a patient will have a diminished maximum specific gravity and normal blood reactions. Should the urinary volume diminish sufficiently in such a patient, he goes into the decom-

pensated stage, in which the lowered maximum specific gravity is accompanied by retention of urinary constituents in the blood. The term renal insufficiency applies strictly only to decompensated cases, just as myocardial insufficiency is used only when such conditions as dyspnea or edema are present. Of course, compensation and decompensation are relative terms, as is the case with the heart, for a patient may be compensated when on a restricted diet but not when eating more.

THE TESTS OF RENAL FUNCTION

In studying the functional ability of the kidney, it must always be kept clearly in mind that deficient excretion of a substance by the kidney is not necessarily the fault of the kidney itself. The kidney is merely one link of a chain which starts with the alimentary canal and ends with the urinary passages, and diminished excretion may be the result of a defect in any link. Thus, chloride may practically disappear from the urine in pneumonia, or urea may be very low in severe liver disease, despite the functional integrity of the kidney. On the other hand, excretion may be completely carried out despite severe functional impairment of the kidney by a compensatory polyuria, or because the intake is so diminished as to be within the powers of the injured kidney.

THE URINARY TESTS OF RENAL FUNCTION

Simple inspection of the urine often affords a very good idea of the functional state of the kidneys if one has the clinical features of the case in mind. Thus, if the urine of a patient with cardiac insufficiency is highly colored and of a high specific gravity, it is practically certain that renal function is good. On the other hand, if the urine of such a patient is light in color and of low specific gravity, it is very probable that the kidneys are severely injured, and further investigation is necessary. Such simple inspection of the urine in a comatose hypertensive patient will often enable one to rule out uremia. Similar considerations apply to patients who are vomiting, sweating profusely or forming ascites as a result of cirrhosis of the liver. In all instances in which there is prerenal deviation of water, the urine should be of high concentration, and if it is not one must look for impairment of renal function. Conversely, if the patient is absorbing edema or a serous effusion, the heart is improving as a result of digitalization, or the patient is drinking copiously, the urine may be very dilute despite intact kidneys. Nocturia in a patient not suffering from myocardial insufficiency should always cause one to look for renal mischief.

Almost all the urinary tests of renal function are of two varieties, balance tests and concentration tests.

BALANCE TESTS

In balance tests, a known quantity of some substance which is excreted in the urine is given either by mouth or by injection, and the quantity eliminated in the urine in a given time is measured. Balance tests with urea and sodium chloride were extensively used, but now the most popular form of balance test is that carried out with dyes, which can be estimated by simple colorimetric procedures in the urine, removing the necessity for troublesome chemical determinations. Of these phenolsulphonphthalein seems to be the best, and has been almost exclusively used in this country since its introduction by Rowntree and Geraghty.[4]

In the phenolsulphonphthalein test, the total excretion of the dye in two hours is measured. But it has been shown in the foregoing section that good excretion does not necessarily mean good renal function, while poor excretion is not always indicative of poor renal function. In cardiac failure the output of phenolsulphonphthalein may be as low as in very severe renal diseases. On the other hand, the normal quantity of the dye may be eliminated in two hours in the compensated phase of impaired renal function, despite severe injury to renal function. I have many times seen a phenolsulphonphthalein output of 50 per cent, even 65 per cent, in two hours in patients with contracted kidneys who were unable to concentrate above 1.010. The compensatory mechanism that keeps the chemical condition of the blood normal in these cases also serves to secure adequate excretion of phenolsulphonphthalein. Phenolsulphonphthalein is a substance which is normally highly concentrated by the kidney, and when renal function is impaired the concentrating power for the dye, as for all other substances, is decreased. However, it may nevertheless be excreted in normal amount, though in greater dilution, despite the impairment of renal function. In accord with this, Snowden[5] has shown that, in severe functional impairment of the kidney, the phenolsulphonphthalein output varies more or less directly with the volume of the urine and can be increased by the free administration of water. I have repeatedly observed this phenomenon; and those who endeavor to "stimulate better excretion" by having the patient drink several glasses of water before injecting the dye are merely masking the impairment of renal function, if this is present.

For these reasons I do not believe the phenolsulphonphthalein test to be nearly as instructive as the concentration tests, which show specifically whether or not the function of the kidney itself is disturbed. The same holds for the innumerable other balance tests with foreign substances—potassium iodide, sodium salicylate, sodium thiosulphate, various dyes and diastase—or with such normal urinary constituents as urea, sodium chloride or creatinine. All suffer from the same defect—they measure excretion in the urine, which may be diminished as a result of either renal or extrarenal causes, or maintained at a good total despite markedly injured kidneys, without the possibility of differentiating by these tests alone.

CONCENTRATION TESTS

The theory of the concentration test is to place the patient under conditions which cause the normal person to elaborate urine containing one or more constituents in high concentration, and observe whether the patient is able to attain this concentration. Since the concentration tests study the very nature of impairment of renal function, diminution in concentrating power, I believe them to be, in general, the best tests of renal function available at present.

The urea concentration test of Maclean and de Wesselow[6] consists in giving the patient 15 Gm. of urea by mouth and estimating the percentage of urea in the urine one hour and two hours later. If the kidneys are healthy, the urea concentration exceeds 2 per cent. If renal function is seriously impaired, the urea concentration is less than 2 per cent and may be under 1 per cent. The urea concentration test is correct in principle

[6] Maclean, Hugh; and de Wesselow, O. L. U.: On the Testing of Renal Efficiency, Brit. J. Exper. Path. 1: 53 (Feb.) 1920.

—for because of the unitary nature of impairment of renal function, if the urea concentrating power is impaired, the same holds true for the other urinary constituents—and is undoubtedly one of the best available methods for studying renal function. However, though exceedingly simple in execution, it requires a chemical determination in the urine. As equally good results can be obtained with the specific gravity test, involving only the determination of the specific gravity of the urine, I believe the latter to be better suited for general use.

The specific gravity test was first popularized by Volhard.[7] His procedure consists in giving the patient 1,500 cc. of water to drink within three quarters of an hour in the early morning, and then nothing but a dry diet for the rest of the day. Following the ingestion of the water, the specific gravity of the urine drops below 1.002, and the amount of water taken is eliminated in about four hours. Later in the day, the specific gravity mounts, passing 1.025 late in the afternoon.

I have found that there are serious disadvantages in performing the dilution and concentration tests on the same day. In the class of patients in whom tests of renal function are most often needed, those with arterial hypertension, there is often a greater or lesser degree of circulatory weakness. In such patients the deficient circulation may prolong the excretion of the ingested water for many hours, so that observation through the day of the test may not reveal the true maximum concentrating power of the kidneys and simulate impaired renal function. For this reason, I perform the concentration test alone, using the following simple method:

> About 6 o'clock of the evening before the test the patient has his usual supper, which should not contain more than about 200 cc. of fluids. After this he neither eats nor drinks anything until the tests is over. Before retiring he empties the bladder; this urine is discarded. On wakening in the morning he passes urine, which is kept in a separate bottle. He remains in bed and urinates one hour later and again an hour after this, each urine being kept in a separate bottle. The specific gravity of each of the three specimens is measured, and the highest taken as the patient's maximum.

The patient has had, with little inconvenience, about sixteen hours in which to concentrate. If kidney function is unimpaired, the specific gravity will exceed 1.025, often going as high as 1.032. As mentioned above, in the severest impairment of renal function the specific gravity is only 1.010, and in intermediary cases figures between these extremes are obtained. In patients with true uremia the maximum is under 1.020, and usually much closer to 1.010. In every case exhibiting low specific gravity, it is important to observe whether edema is being evacuated, for this may simulate inability to concentrate.

I have found this simple variety of concentration test the most generally useful method for studying renal function. It causes so little inconvenience to the patient and so little trouble to the physician and nursing staff that it can be repeated as often as desired. Since adopting the specific gravity test, I have rarely used any other urinary test of renal function.

The dilution test has been briefly discussed. Impaired water excretion in chronic interstitial nephritis is most often of extrarenal origin, being due to the formation of edema or cardiac failure, but, as has been shown, it may be a manifestation of impaired renal function. If the impaired water excretion is due to extrarenal causes, the specific gravity of the urine will be high; if a manifestation of renal failure, the specific gravity test will give a low result. For these reasons the concentration test usually suffices, and we can mostly dispense with the dilution test.

The use of test meals (Schlayer and Hedinger,[8] and Mosenthal[9]) is another variety of concentration test. Here, the changes in the specific gravity, urea and chloride concentration following meals are studied. As equally good information as to the functional state of the kidneys can be obtained from the simple specific gravity test, this more complicated procedure seems superfluous.

THE CHEMICAL CHANGES OF THE BLOOD

Despite severe impairment of renal function, the chemical composition of the blood may be entirely normal—either because the great factor of safety of the kidney has not been exceeded, or because the patient has so adjusted his food intake as not to exceed the functional capacity of the kidneys, or finally because the diminished concentrating capacity of the kidneys is balanced by a relative polyuria. It is obvious that this compensated stage can be detected only by one of the tests of urinary concentration. But for the detection of the onset of decompensation—true renal insufficiency—the chemical condition of the blood must be studied to note the accumulation of urinary constituents in the blood.

Either the blood urea or total nonprotein nitrogen serves as a satisfactory indicator of retention. Creatinine, uric acid and, in Germany, indican are other urinary constituents that are frequently estimated in the blood in studying renal function. As these more complicated determinations rarely afford any information that is not furnished by urea or nonprotein estimations,[10] they can be dispensed with for clinical purposes. The custom which is so widespread in hospitals of determining nonprotein nitrogen, urea, creatinine and uric acid in all patients with kidney disease seems to me to be a great waste of time and money.

It must always be borne in mind that even maximum accumulation of urinary constituents in the blood does not prove that the trouble is primarily with the kidney. Thus, the nonprotein nitrogen of the blood may rise to great heights as a result of severe vomiting or diarrhea, because so much water is thus lost extrarenally that little or none is available for the kidney to excrete the other urinary constituents, though it is perfectly capable of doing so. In such cases the specific gravity differentiates between rentention of renal and extrarenal origin.

SIMULTANEOUS STUDY OF BLOOD AND URINE

By comparing the urea content of the blood and the urine, Ambard[11] has evolved a formula for calculating a constant which, he believes, is a delicate indicator of the efficiency of the kidney. But Maclean[12] has pointed out that Ambard's formula is affected almost entirely by variations in the urea content of the blood, and relatively little by changes in the composition of the urine. The result is that the Ambard constant may be practically normal in the presence of severely impaired renal function, provided it is in the compensated stage. I have seen patients who could not concentrate above 1.012 with the Ambard constant within the normal limits.

SUMMARY

Since impairment of renal function consists in a diminution in the concentrating capacity of the kidney, the most logical and direct tests of renal function are those which measure the concentration of one or more urinary constituents.

The most useful variety of concentration test, requiring no laboratory facilities, is the specific gravity test, for which the technic is simple.

Compensated and decompensated stages of impaired renal function are to be distinguished. In the compensated stage, there is impairment of concentrating power but excretion is completed by a relative polyuria, so there is no retention of urinary constituents in the blood. This stage can be detected by a concentration test. In the decompensated stage, the diminished concentrating power is accompanied by retention.

Tests which measure the quantity of some substance (as phenolsulphonphthalein) excreted are deficient in that they do not detect the compensated stage of impaired renal function. Such tests may yield subnormal results in consequence of extrarenal factors, as cardiac failure, though renal function is intact. Both these errors are avoided by the simple specific gravity test.

THE INCREASE IN HEART DISEASE

PARTIAL EXPLANATION IN INCREASED PROPORTION OF POPULATION INJURED BY CERTAIN INFECTIOUS DISEASES: PRELIMINARY NOTE *

HENRY ALBERT, M.D.
DES MOINES, IOWA

Numerous recent articles have served to call attention to the increasing number of persons who are dying from heart disease.

Thus, in the registration area of the United States, the number of deaths from heart disease per hundred thousand of population has gradually increased from 132 in 1900 to 185 in 1925.

The two reasons that have been given for this increase are the strenuous life of today and the increased length of life, which permits more people than ever before to reach the "heart disease" age.

I herewith present an explanation for at least a portion of the increasing mortality from heart disease. It is a reason which, so far as I know, has not before been presented. This explanation furthermore offers great hope for a reduction—possibly a considerable one—in the number of cases of this disease in the course of the coming years.

Heart disease is in large part the result of injury to that organ by an infection that occurred some years previous. There is, at the present time, a greater proportion of our population which has been maimed by scarlet fever and probably also many other diseases, including rheumatic fever and syphilis, than there were ten or twenty years ago.

In the accompanying table are presented the morbidity and mortality rates from scarlet fever per hundred thousand of population in Massachusetts from 1880 (mortality) and 1895 (both mortality and morbidity) to 1926.

Mortality and Morbidity Rates from Scarlet Fever

Year	Morbidity Rate	Mortality Rate
1880	(Not available)	32.1
1885	(Not available)	30.2
1890	(Not available)	8.8
1895	243.7	19.3
1900	227.9	11.8
1905	136.4	3.9
1910	233.2	7.5
1915	232.3	4.9
1920	265.2	5.5
1925	248.2	2.8
1926	268.4	(Not yet available)

It will be noted that whereas there has been no particular change in the morbidity rate there has been a marked reduction in the mortality. This speaks very highly for the effective work of the physician in the treatment of this disease, although the decrease may be partly explained by a more mild type of infection.

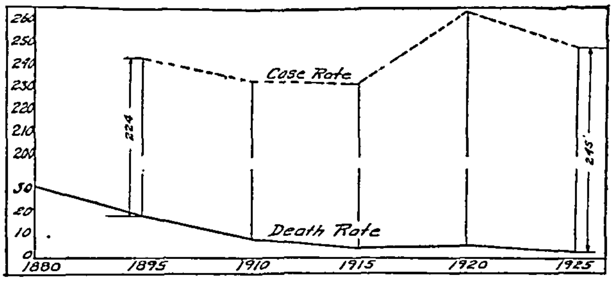

Chart 1.—Case and death rate of scarlet fever in Massachusetts, per hundred thousand of population, from 1880 (and 1898) to 1925. Whereas there has been an actual increase in the case rate, there has been a marked reduction in the death rate, leaving a larger proportion of persons maimed by the disease in 1925 than in 1895.

This means that whereas in 1895 there were 224 out of every 100,000 persons living in Massachusetts who survived an attack of scarlet fever that year, in 1925 there were 245 persons per hundred thousand of population who thus survived (chart 1). All who survive an attack of scarlet fever are probably more or less maimed by it. The injury done may not become apparent until twenty or more years later, when it may reveal itself in the form of disease of the heart, kidneys or other organs.

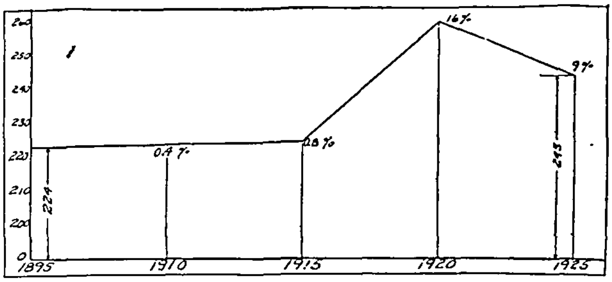

Chart 2.—Number of cases of scarlet fever per hundred thousand of population in Massachusetts which did not prove fatal but in which, by virtue of having had the disease, the persons concerned were presumably somewhat injured. The increase from 224 in 1895 to 245 in 1925, was an increase of 9 per cent. There was a progressive increase in practically every year after 1895. The cumulative increase for the twenty year period is about 50 per cent.

In 1925 the proportion of the population of Massachusetts that was presumably injured by scarlet fever that particular year was 9 per cent higher than in 1895 (chart 2). Considering that the increase in the number of maimed has been progressively higher for almost every year during the last twenty years, the cumulative increase is estimated as being about 50 per cent.

---

* From the State Department of Health, Des Moines, Iowa.

* Read before the joint annual meeting of the Iowa Tuberculosis and the Iowa Heart Associations at Des Moines, Iowa, Feb. 23, 1927.

Even though only a comparatively small proportion of the deaths from heart disease may be due to scarlet fever, the increase in the proportion of the population which has been maimed by this disease may very well explain a portion of the increase in the total number of deaths from heart disease.

Data are now being gathered with the idea of demonstrating the same point in connection with other diseases.

THE TALLEST AMERICAN BOYS *

HORACE GRAY, M D.
CHICAGO
AND
S T NICHOLSON, M D
POTTSTOWN, PA

Brailsford Robertson,[1] who has given so much attention to growth, says. "To compare groups of children in regard to physical welfare we should compare their average statures and the variabilities thereof "

In a recent paper [2] offering to those who work with boarding and country day school boys averages compiled from observations on that special class of individual, the statement was made that the average exceed in stature the gifted children reported by Baldwin [3] as being "above the best standards for American born children in physical growth status." Owing to the interest and importance attached to height, our statement is worth further evidence

In table 1, accordingly, are shown statistical constants reduced from our raw data, including the mean stature for each age as published in the paper just cited. For comparison we have translated Baldwin's means into metric equivalents and have computed the probable errors of those means; these are not reproduced. In table 2 are instituted the comparisons, for each age group, between the mean heights in the two series. The differences we have used without "weighing" (that is, without multiplication by the number of individuals at that age, because that number was not the same in the two series). It is clear in table 2 that the boarding school boys are equal to or taller than the California gifted at all ages. The advantage in stature amounts at some ages to 3 3 cm., or 2.4 per cent above the average height for that age of the California gifted, with an average for all ages of 1.9 cm., or 1.4 per cent. Though relatively small these differences are to be regarded as significant, in the first place because of the fact that the height of the boarders is not exceeded at any age, and secondly in view of the biometric ratio difference between means, divided by probable error of this difference (Diff./P. E. of Diff.). The ratios indicate that:

TABLE 2—*Figures Showing that Eastern Boarding School Boys Are as Tall as or Taller Than the "California Gifted" Boys at All Ages*

Age Nearest Year	Difference Between Means in the Two Series at Each Age, Cm.	Probable Error of Difference	Ratio: Diff /P E. of Diff.
7	0 8	±1 450	(0 5)
8	1 7	±0 903	(1 9)
9	2 7	±0 764	3 5
10	3 3	±0 768	4 3
11	0 0	±0 761	(0)
12	2 2	±0 913	2 4
13	0 5	±0 954	(0 5)
14	3 0	±1 138	2 6
15	3 2	±5 536	(0 6)

Parentheses around ratios indicate that these are not significant.

(*a*) The boarders at ages 7, 8, 11, 13 and 15 are not mathematically proved to be taller.

(*b*) The boarders at ages 12 and 14 are probably significantly taller

(*c*) The boarders at ages 9 and 10 are definitely taller.

Another tall series worth comparing consists of Holt's [4] average of 1758 observations on 350 boys in a private school (Browning) in New York City. These means have been inserted in table 1 since we believe that they have never been published. The average height of our 1,016 boarders is greater at ages 11, 12 and 14, while at ages 13, 15, 16 and 17 the city private boys excel. The general average difference, with regard to size, is in favor of the boarders by 1.2 cm., or 1.4 per cent, above the city private boys.

Still another tall series, by Benedict and Talbot,[5] covers 886 boys from eight New England private

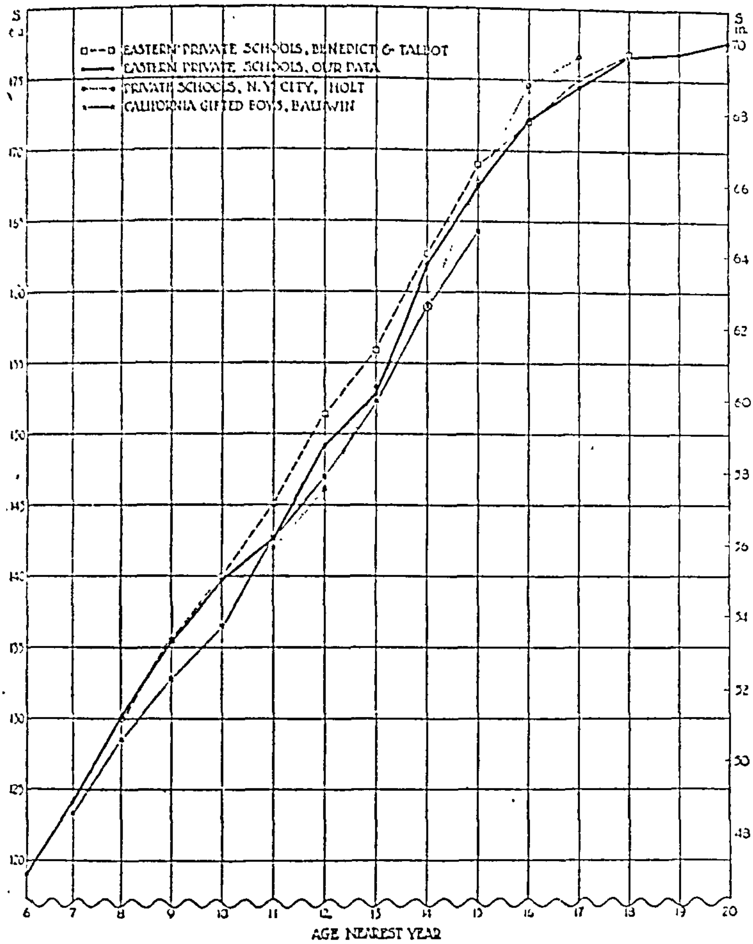

Chart 1.—The tallest American boys.

schools. As the numerical averages were not published, but only a diagram, Dr. Benedict has been kind enough to lend the original drawings, 14 by 10 inches; and from these the average statures have been picked off with dividers and engineer's rule. The accuracy of this procedure is indicated by the fact that the readings as made from the drawing by two of us seldom differed by as much as 2 mm. and never by more. These published means are inserted in table 1. The average height of the Benedict and Talbot private school boys exceeds ours at ages 10, 11, 12, 13, 14, 15, 17 and 18, not at 8, 9 and 16, the general average difference in their favor being 1 cm., or 0.6 per cent. Furthermore, their series has the advantage of Holt's at ages 11, 12, 13, 14 and 15, not at 16 and 17, with this time an average difference in their favor of 1.7 cm., or 1.0 per cent. The record then seems to be with them, although the possibility that this may be due to random sampling cannot be excluded owing to lack of data on the probable errors of their means.

Finally, a recent public school series may be selected for comparison, for example Faber's[6] on San Francisco public school boys. By Professor Faber's kindness, these unpublished figures are included in table 1. Here considerably greater differences are to be expected. The boarders exceed the public school boys at varying ages by from 3.1 to 10.6 cm. (or from 2.1 to 6.6 per cent), with a general average of 6.6 cm. (or 4.7 per cent).

VARIABILITY

The standards of normal variation now in general use are far from satisfactory, according to Faber[7] in a recent report on variability in weight. We shall therefore proceed to some evidence on variability in height. The variability in the stature of boys at a given age may best be measured by the standard deviation (S. D. or σ) expressed in percentage of the mean stature (M); that is, 100 S. D./M.

Comparison with reported coefficients of variability is difficult owing to the scarcity of these.[8] As against two recent series of Baldwin's, our boys' heights evidently vary less (chart 2).

The well known great variability of children at certain ages is apparent in our series. The lowest coefficient of variability was 2.68 at age 8 (omitting ages 6 and 20 because the number of cases in each group was only nine), and the highest coefficient of variability was about twice as great; namely, 5.34 at age 14.

Regarding the fluctuation in the variability at different ages, the curve for the California gifted boys behaves unevenly and differently from the other two curves. Baldwin's Horace Mann curve and our curve show excellent parallelism at age 12 and later (puberty), and though not satisfactory at earlier ages, show striking similarity in the peculiar decrease in variability at age 8, followed by a rise at age 9 and drop again at age 10.

CONCLUSIONS

Even so simple a question as what group of American boys is tallest seems answerable at present only in part: private school boys. More data are necessary to

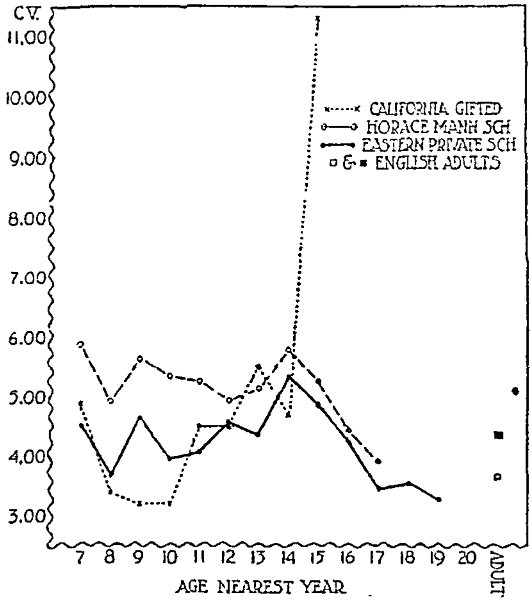

Chart 2.—Variability of height at different ages.

Case 6.—F., a man, aged 24, was treated at intervals over a period of ten years for recurring attacks of prostatitis in which no evidence of venereal disease could be found. The cultures from the prostate showed *Streptococcus viridans.* Finally, roentgenograms of the teeth showed two very badly diseased roots, which were removed. Cultures taken immediately from the apexes showed pure *Streptococcus viridans.* Following the extraction of the teeth there was an immediate aggravation of the prostatitis. This rapidly subsided and was well in three weeks without any local treatment. The patient has remained perfectly well now for three years.

Case 7.—A young school teacher came to me because there was pus in the urine following an attack of pneumonia. I found the prostate to be the source of pus, which showed *Staphylococcus aureus.* A roentgenogram of the teeth showed three very bad ones, which were removed. Cultures taken from the root apexes showed *Staphylococcus aureus* and *Streptococcus viridans.*

COMMENT

During the spring and summer of 1926, I saw, in consultation, six cases of acute epididymitis associated with or following attacks of so-called influenza. Unfortunately, cultures were not obtained; but careful study of smears did not show gonococci, nor was there a history of venereal infection. It was assumed that these cases were secondary to the epidemic of influenza-like infection prevalent at that time. However, one must in such cases always suspect that, in some at least, the febrile reaction was only a manifestation of the onset of a deep genital infection; and the acute epididymitis was merely an extension of the infection from the diseased vesicles. Genital infection complicating influenza, however, has been noted by several investigators, Bugbee[2] reported five such cases with prostatic abscess, in one of which the influenza bacillus was found in the prostatic pus.

The importance of recognizing nonvenereal genital infections is quite evident, and the prevailing idea, among physicians as well as the laity, that genital infection means venereal disease must undergo a very radical change. This common idea is somewhat excusable because of the lack of information on the subject both in textbooks and in the literature, and because of the universal prevalence of venereal disease.

Up to 1925 I was able to find only one article calling attention to the subject—that of G. G. Smith,[3] who reported forty cases of nonvenereal prostatitis. This seems almost incredible, for nonvenereal infection has long been recognized by urologists. Since the papers of Smith and myself were published, W. H. von Lackum[4] of the Mayo Clinic has presented and published several very important papers on the subject, calling particular attention to the frequency (24 per cent) of nonvenereal genital infection, and emphasizing the importance of focal infection as an etiologic factor. He further checked his cases by animal experimentation, and was able to reproduce in rabbits many of the typical secondary complications found in his patients by inoculating the animals with the infected prostatic secretions.

Although nonvenereal infections may simulate the venereal type symptomatically, one who has compared a large number of the two types will note some marked differences in the pathologic changes. In the nonvenereal infection of the prostate I have frequently noted that, in spite of a swollen, indurated and tender gland, there may be only a few or no pus cells in the expressed secretion; but if the gland is massaged a day or so following dilation of the prostatic urethra, in such cases one will usually get a copious purulent secretion. Others have made the same observation and advise that, in all patients suspected of harboring infection in the prostate and seminal vesicles, the prostatic urethra be moderately stretched and mildly stimulated with silver nitrate one or more times before these parts are excluded as foci of infection.

I believe that the difficulty thus occasionally experienced in demonstrating infection in the deep genital organs is more frequent in the nonvenereal type, and is due in great part to the manner by which the bacteria are carried there. Thus, when carried to these parts by the blood (or lymph) stream, the bacteria are lodged in the interstitial tissues, where they may cause either an acute or a low grade indolent infectious process. It is only later, and by direct extension, that the infection reaches the gland acini and ducts; while even before this happens one may find a marked periprostatitis or perivesiculitis due to early extension into the serous coats. The infection, being locked in the interstitial tissue, and in close apposition to the blood and lymph capillaries, has thus no natural path for drainage, and slow absorption or abscess formation is to be expected. The counterpart of this is seen in metastatic renal infections, which, as has been so well demonstrated by Cabot and Crabtree, are most frequently seen localized primarily in the renal cortex and about the glomeruli, breaking into the parenchyma or perirenal tissues later. This is noted as characteristic of the coccal infections, while the bacillary infections are most commonly found involving the renal tubules and pelvis.

Venereal infection gains the prostatic acini and seminal vesicles by direct extension along the excretory canals and ducts, involves the interstitial tissue and serous coats later, and is thus less prone to abscess formation because of the natural drainage afforded.

COMPLICATIONS OF NONVENEREAL INFECTION

The importance of nonvenereal genital infection to medicine and surgery is demonstrated by the various remote symptoms and complications which they so frequently cause. Since focal infection has been given such an important rôle, especially through the pioneer work of Billings and later of Rosenow, the prostate and seminal vesicles have been looked on as frequent sources of such infection. However, I have attempted to emphasize, in the studies which I have made, that these structures, frequently found responsible for remote symptoms and complications, owe their disease condition to foci in other parts; but, once being infected, they may continue to shower the system with virulent disease-producing organisms even after the primary foci have been eradicated. Conversely, I do not believe that treatment of the diseased nonvenereal prostate will result in any lasting benefit unless the primary foci are removed.

Among these remote symptoms and complications, pain is the most common and may be referred to various parts. In the lower back it may simulate sacro-iliac disease; in the loin it may be, and frequently has been, mistaken for renal disease, so much so as to have prompted surgical exploration of the kidney in a number of instances. The same may be said of pain, acute and chronic, referred to the lower right quadrant of the abdomen and causing a mistaken diagnosis of appendicitis. I have records of three such cases in which the patients were sent in for appendicitis, but because of prompt action by the surgeon in having the seminal vesicles investigated, the true cause of the pain was revealed and operation avoided.

[4] Von Lackum, W. H.: Clinical and Experimental Data on Prostatic Infections, read before the American Urological Association, Boston, in May, 1926.

The pain may radiate down the leg so as to simulate sciatica, but absence of tenderness along the nerve should arouse suspicion as to the referred character of the pain.

Arthritis is perhaps the most common complication of genital infection, both venereal and nonvenereal. Among my series of nonvenereal cases (now more than 150), it was present in 12 per cent. I noted, however, that the arthritis in these cases differed from that seen in gonorrheal infections by being, as a rule, multiple, involving a number of joints, which was in marked contrast to the arthritis of gonorrheal origin, which generally involves only one or two joints at a time. Also, the nonvenereal joint involvement was usually subacute or chronic, in marked contrast to the gonorrheal, which is acute, painful and accompanied by marked swelling in the early stage.

Pyelitis was noted as a complication in 14 per cent of my first sixty-seven cases, and was diagnosed by ureteral catheterization. In this group, one would reasonably question the possibility of the prostatic infection being secondary to the renal infection (descending infection); but, on the other hand, it is possible that the renal infection and genital infection could have occurred simultaneously by metastasis from distant foci, or that the renal infection could be caused by: (1) extension by way of the lymphatics between the deep genital structures and the kidney, or (2) by obstruction of the ureter where it crosses the seminal vesicle, causing partial renal stasis. I believe that the latter explanation holds in many of these cases; and this opinion is supported by the observation of Goldstein and others who have found perivesicular infiltration a frequent cause of ureteral obstruction. While renal infection has been noted frequently in nonvenereal infections of the prostate and vesicles, it is most interesting and instructive to recall that this complication is extremely rare in venereal infections in the male.

Iritis as a complication was present in three of my cases. One of these cases was of peculiar interest, and concerned a young man who, without a venereal history, had suffered with a severe iritis for three months before I saw him. He had had previous examinations of the prostate, which were negative. The only focus of infection was a mild sinusitis. I did not obtain pus from the prostate on the first test; but two days after dilating the prostatic urethra, massage expressed a profuse purulent secretion, which was sterile on smear and culture. I never found tubercle bacilli or any other organisms, yet treatment of the prostate was successful in clearing up the iritis.

Keratitis is another eye complication which I have seen definitely due to the genital infection and which has been noted by others.

Many of these patients present a peculiar mental disturbance varying from a mild anxiety neurosis, apprehensiveness and unwarranted worry to a severe mental depression characterized by morbid ideas which occasionally leads to the putting of these ideas or impulses into real action. I have never seen this mental state exhibited in cases of chronic venereal infection or in cases of benign prostatic adenoma; but I have seen it in marked degree in cases of cancer of the prostate. The explanation of this peculiar complication must be left out of the discussion.

The importance of these infections in relation to prostatic surgery will no doubt be more evident as more study is given to the subject. There are undoubtedly many cases of nonvenereal prostatitis in old men in which the symptoms simulate those of prostatic adenoma and carcinoma, and these should be readily recognized if proper attention is given to a thorough study of each case. I have records of fourteen cases of this type, in all of which the patients are progressing well by treatment directed toward reduction of the inflammatory congestion which caused either partial or complete obstruction.

Operation in such cases is accompanied by much more danger than is the case with uncomplicated benign adenoma.

TREATMENT

The treatment of nonvenereal genital infections consists, briefly, in removing distant foci of infection, and in attention to the local trouble. In acute cases suppuration must be carefully looked for, and when it occurs should demand immediate drainage.

The acute epididymitis, if allowed to go too long, is prone to involve the testis and thus require complete amputation. When it is necessary to do this, the vas deferens of the healthy side should at the same time be divided between ligatures in order to prevent descending infection on that side.

A prolonged unresolved epididymitis should be treated by excision of the epididymis under local anesthesia, care being taken to avoid injury to the testis. Some of these cases are very difficult to differentiate from tuberculous infection, and this fact also should lead one not to delay too long.

The prostate and vesicle infection is best treated by the usual method of massage, sounds and irrigations, but heat applied through the rectum by hot douches is one of the most valuable procedures. Diathermy is also useful, and judging from what experience I have recently had with it, I am inclined to believe that it has great possibilities. Vaccines are sometimes very efficient, but in acute cases must be used cautiously, else the effect may be aggravating rather than alleviating. In hard infiltrations, I have found intravenous administration of sodium iodide an excellent remedy. I have used mercurochrome-220 soluble intravenously without seeing any marked benefit, although careful checking of the urine after its use never showed any harm done.

I think that it is of extreme importance to treat these cases in the acute stage with the most respectful gentleness, avoiding too early or too vigorous massage; and, above all else, not meddling with instruments, especially the cystoscope, in order to satisfy one's curiosity with regard to the kidneys. I learned to observe this rule in the management of my first series of cases, which showed 14 per cent of renal complications. It is only too well known that urethral chill, following instrumentation, means a lighting up of an existing renal infection by showers of bacteria from the prostate.[5] Only in extreme cases should cystoscopy be done, and then only after thoughtful consideration.

CONCLUSIONS

I believe that there is ample justification for the following conclusions:

1. Nonvenereal genital infections are much more common than has been realized, and focal infection in other parts is an important etiologic factor.

---

[5] Keyes, E. L.: Urology, New York, D. Appleton & Co.

2. The prostate gland and seminal vesicles, once infected by metastasis, may continue as important foci for spreading the original infection, thus causing remote pains and symptoms easily mistaken for other conditions.

3. The importance of these diseases in their relation to prostate surgery cannot be overlooked, because by proper recognition and treatment of the infection many major surgical operations may be avoided.

4. Although the nonvenereal infections may simulate those of venereal origin symptomatically, there are certain differences in the pathologic changes, based on the etiology, which render the former class much more resistant to treatment and more responsible for complications.

5. That a patient with prostatic infection has had venereal disease some years previously is no reason why his present trouble should be attributed to this old infection in the absence of positive tests; rather, one should consider such cases to be of metastatic origin.

THE TREATMENT OF EPILEPSY IN CHILDHOOD

FIVE YEARS' EXPERIENCE WITH THE KETOGENIC DIET [*]

HENRY F. HELMHOLZ, M.D.
ROCHESTER, MINN.

Since 1922 I have given children with idiopathic epilepsy a diet sufficiently high in fat to produce ketosis, as manifested by diacetic acid in the urine. Originally, the diet was tried in order to maintain the ketosis that possibly was responsible for the good therapeutic effect of starvation, but it was soon found to have a more definite curative effect than starvation. The diet, which was originally worked out by Wilder,[1] gave striking results from the first. Even the skeptic was convinced of its efficacy by seeing attacks of petit mal occurring hourly disappear with the establishment of adequate ketosis, and return if for some reason the diet failed to produce the necessary degree of ketosis. That the greater number of epileptic patients would not be affected was to be expected, in view of the fact that the nature of the disease is unknown. The preliminary results promised definite improvement in the treatment of idiopathic epilepsy. The results of the first two and a half years' treatment in the Mayo Clinic were reported in 1925 by Peterman.[2] The time interval in many cases was of necessity too short for a determination of the ultimate outcome, and a review at the present time shows that the results as published are not quite so successful as they were pictured. Of the thirty-seven cases in Peterman's series, convulsions have not recurred in ten.

What shall be called a cure? Is a patient who is free from attacks while in ketosis cured, or must he remain free from attacks after he returns to a normal diet? How shall those patients be classified who are free from attacks while on the ketogenic diet but whose symptoms return as soon as there is a break in it? How shall those be classified who remain free from attacks for six months or more after resumption of a normal diet and then suffer from a return of symptoms? Classification has been difficult, particularly because the patients have been under direct observation only for a short introductory period, and in some cases for occasional control periods. It seems fair to assume that a considerable number of failures is due to inability to control the diet properly, but in order to present the figures as fairly as possible I have counted as failures all cases in which there was not definite improvement after two months or more of the ketogenic diet without the addition of medication. The diet is not easy to carry out, and if it appears to the parents that the results are not definitely favorable after a period of trial, it is difficult to induce them to continue giving it to the child.

COMMENT

One hundred and forty-four young patients have been treated with the ketogenic diet. Twelve of these suffered from symptomatic epilepsy complicating encephalitis and cerebral palsy, and were treated for the most part at the parents' request. Enough improvement has occurred in this group to demonstrate that the treatment is worth a trial, even though the percentage of cures is decidedly lower than in cases of idiopathic epilepsy. Two patients are free from attacks, six are definitely improved, and only four are unimproved. The number of patients with symptomatic epilepsy who have been treated is too small to allow any decision with regard to treatment, but experience so far warrants its further trial (table 1).

Of the 132 cases of idiopathic epilepsy, seventeen were observed in the last six months and are therefore not included in the tabulations of results. Five of the latter showed temporary improvement while under observation, three were unimproved, and the attacks of the remaining nine were not frequent enough to permit conclusions regarding the results.

Twenty-four cases are unclassified (table 2). In this group of patients are included those who were free from attacks for a long period and then suffered from a return of the attacks, and whose state of ketosis was questionable, and those for whom phenobarbital (luminal) was required along with the diet to control the attacks. A large number of these patients did not keep in touch with the clinic, and a number of them improved while under observation but did not attain a state of ketosis at home. These cases are presented merely in order to tabulate all the cases treated. The information obtainable was not clear-cut enough to justify listing them as failures. They are not included in the tabulation of results.

Ninety-one patients have been on the diet long enough to give a definite idea of the effect of ketosis on the number and severity of convulsive seizures. The diet did not seem to have produced a therapeutic effect in forty-two (46 per cent) of the ninety-one patients (tables 3 and 4). Some of the children made temporary progress, but it was soon evident that the diet alone was not of any great value. In twelve instances there is a question as to the degree of ketosis attained after the patient returned home, but in the others ketosis was sufficient to produce a positive reaction of the urine with ferric chloride, according to Gerhardt's test. Of these forty-two patients only thirty were having attacks frequently enough so that the effect of ketosis could be noted while they were under observation at the clinic. Fourteen of the thirty were temporarily improved; the other twelve indicated early the ineffectiveness of the diet.

Forty-nine patients (54 per cent) were definitely benefited by the diet (tables 5 and 6). In some cases the number of attacks was markedly reduced and the intervals between them were lengthened. The convulsion in the grand mal attacks was decreased in severity. Patient 30 was free from attacks for seven months and then had one attack. No further report has been received. In case 89, the attacks were controlled with phenobarbital and diet for a time. About three months after the phenobarbital was discontinued the attacks ceased, and there has not been any recurrence to date (two months).

Table 1.—*Cases of Symptomatic Epilepsy*

Case	Age	Sex*	Diagnosis	Frequency of Attacks	Duration	Placed on Diet	Comment
				Epilepsy on Basis of Encephalitis			
114	9	♂	Grand mal Petit mal	Every two or three days....... Occasional	7 years	8/19/25	Improved on diet for six months; grew worse; phenobarbital added but no improvement
115	5	♂	Grand mal Petit mal	Every two or three months.... Three to ten daily	2 years	7/ 2/25	Attacks less frequent and less severe; general condition better
116	5	♂	Grand mal	Every two weeks..............	6 months	9/ 1/24	Attacks at intervals of five months; now on general diet
117	5	♂	Grand mal	Every two months............	4 years	4/25/25	Free for periods of six months; mentally retarded
118	4	♂	Grand mal	Series every two weeks.........	4 months	12/26/25	On diet two months with no improvement; general diet and phenobarbital controls
119	3	♀	Grand mal	Two to eight daily............	18 months	7/ 9/25	On diet; no attacks since October, 1925
				Epilepsy on Basis of Cerebral Palsy			
120	3	♂	Grand mal Petit mal	Four every three months....... Ten to twenty hourly	1 year	6/22/24	No grand mal attacks but petit mal continued; still on diet; marked mental retardation
121	11	♀	Grand mal	One to two yearly.............	3 years	6/12/25	Complete freedom since addition of phenobarbital; diet nearly normal
122	7	♂	Grand mal Petit mal	One to two weekly............. Two to ten daily	3 months	10/22/21	Phenobarbital, acidophilus milk, and ketogenic diet tried in turn; fewer attacks on diet and phenobarbital
123	12	♂	Petit mal	One to two daily..............	? years	9/ 6/23	No attacks when in ketosis; patient uncooperative
124	11	♀	Petit mal	Ten to twenty daily...........	10 years	11/23/25	Attacks less frequent but in series; free for four months at one time
125	9	♀	Grand mal Petit mal	Two to three daily............ Two to three daily	1 year	7/16/25	No attacks since October, 1925; on normal diet one month later

* In this column, ♂ indicates male; ♀, female.

Table 2.—*Unclassified Cases*

Case	Age	Sex	Diagnosis	Frequency of Attacks	Duration	Diet Continued	Comment
90	14	♂	Grand mal	Three in all.....................	1 month	1 year	Free for eight months, then attacks began
91	8	♀	Grand mal	Five in all......................	1.5 years	6 months	No attacks but received phenobarbital
92	9	♀	Grand mal Petit mal	Five in all...................... Five to six every two weeks	7 years	1 year	Diet not consistently followed
93	8	♀	Petit mal	Eight to ten daily............	3 years	9 months	Diet never correct
94	15	♂	Grand mal	One every month..............	7 years	3 to 4 months	Urine never positive
95	13	♂	Grand mal	One to two each month........	9 months	3 months	Diet incorrect, soon abandoned
96	12	♂	Petit mal	Ten to twelve daily...........	3 years	15 months	Good result in hospital, but would not cooperate at home
97	14	♂	Grand mal Petit mal	Occasional .... Series every two weeks	7 years	6 weeks	Diet never correct at home.
98	6	♂	Petit mal	Ten to twelve daily............	11 months	?	Never wrote after leaving clinic
99	5	♂	Grand mal	One daily	4 years	3 months	Diet not well tolerated; now on general diet and phenobarbital
100	4	♂	Grand mal Petit mal	Three to four each month..... Four to twenty-five daily	2 years	?	Diet not tolerated; free for year and a half on phenobarbital
101	9	♀	Grand mal	Occasional	3 years	?	Phenobarbital had controlled attacks; on diet only short time, then returned to phenobarbital
102	13	♂	Grand mal	Two to three daily............	17 months	?	Diet possibly for few weeks
103	5	♀	Petit mal	One to four daily.............	2 years	3 months	Diet not well tolerated and abandoned in few months; ketosis ?
104	9	♂	Grand mal	Two each month...............	6 months	?	Not heard from since leaving clinic
105	8	♀	Petit mal	Five to ten daily..............	4 years	6 months	Ketosis not present at home
106	13	♂	Grand mal	One to two daily..............	2.5 years	3 months	Phenobarbital added; possible organic lesion
107	13	♀	Grand mal Petit mal	One every two or three days... One every two or three days	2 years	?	No reply to our letters
108	11	♂	Petit mal	Two to three every two or three days	5 years	6 to 7 months	Appendicitis interrupted diet; did not return to it; no further reports
109	11	♀	Grand mal Petit mal	One every year................. Eight to ten daily	4 years	4 months	No improvement first month but diet not well managed; no further reports
110	6	♀	Grand mal	Three to four daily...........	4 years	?	No improvement but tests negative
111	8	♂	Grand mal	Three to four daily...........	5 years	2 months	No improvement; no ketosis
112	12	♀	Grand mal	Four to five daily.............	Life	1 month	No improvement but no ketosis
113	9	♀	Petit mal	Ten to twelve daily...........	2 years	To date	Never in ketosis

Table 3.—*Failures*

Case	Age	Sex	Frequency of Attacks	Duration	Diet Continued	Ketosis	Comment
				Petit mal			
48	11	♀	One hundred daily............	Life	16 months	Yes	Bromides beneficial
49	14	♀	One each week................	3 years	2 years	Periodic	Free once for three weeks
50	3	♀	Twenty to twenty-five daily...	9 months	To date	Yes	Phenobarbital added, fewer attacks
51	9	♀	Fifty to sixty daily..........	5 months	1 year	Yes	Off diet now, no more attacks
52	9	♀	Series periodically	7 years	4 months	?	Attacks became more severe
53	8	♀	Ten to twenty daily..........	6 months	1 year	Yes	No change
54	9	♂	One every week...............	16 months	7 months	Yes	No change; no further reports
55	3	♂	Forty to fifty daily..........	1 year	11 months	Yes	Attacks the same, but general condition improved
56	15	♀	One to twenty daily..........	1 year	10 months	?	No reduction in number; off diet
57	4	♀	Five to six daily.............	11 months	5 months	Yes	No reduction even with phenobarbital
58	14	♂	One to fifteen daily..........	7 years	18 months	Yes	On general diet, attacks same as before
				Grand mal			
59	8	♂	Three to five daily............	2 years	Unknown	....	Child institutionalized
60	13	♂	Series every six months.......	4 to 5 years	16 months	Yes	Practically free, on phenobarbital now
61	8	♂	One every two weeks.........	2 years	3.5 months	Yes	No improvement; off diet now
144	13	♂	Two every month..............	2 months	6 months	Yes	Attacks not reduced; controlled on phenobarbital for past year

Ten patients are without attacks when in a state of ketosis, but there are constant breaks in diet. Various factors are responsible for the breaks. A recent case of petit mal is illustrative. A girl, aged 13 years, was having about fifteen attacks daily. After the diet was started the attacks gradually decreased in number, and after two weeks there were two days of entire freedom from them. Then, without apparent change in the diet, she had five attacks. The urine, which was frankly positive to the test the days she was free from attacks, was negative the day she had five attacks. At first the child denied having eaten anything not included in her regular diet, but later confessed to having eaten some candy. Similar occurrences have been noted in other cases and at the clinic. If attacks occur after such prompt relief, they are almost certainly caused by a break in diet. Talbot[3] has described similar cases.

Table 4—*Cases of Grand Mal and Petit Mal: Failures*

Case	Age	Sex	Diagnosis	Frequency of Attacks	Duration	Diet Continued	Ketosis	Comment
62	10	♀	Grand mal Petit mal	One every two months..... Four to five daily	7 months	3 months	?	Phenobarbital added; no improvement; mental change
63	7	♀	Grand mal Petit mal	Occasional .... Four to five daily	3 months	6 months	Yes	Phenobarbital added; no benefit
64	14	♀	Grand mal Petit mal	Two in all.... .... One to two every week	1 year	To date	Yes	Apparent improvement at first; phenobarbital necessary now
65	9	♂	Grand mal Petit mal	Two to three every month. Twelve to fifteen daily	5 years	7 to 8 mos.	?	No cooperation from patient, phenobarbital necessary
66	10	♀	Grand mal Petit mal	One every day .... Three to five daily	4 years	9 months	?	At first attacks were associated with breaks in ketosis
67	10	♂	Grand mal Petit mal	One to three every night... Twelve to fifteen daily	3 years	5 months	Yes	Diet not well tolerated, phenobarbital necessary
68	11	♀	Grand mal Petit mal	One every year............ Four to five daily	6 years	1 year	?	Failure due perhaps to lack of cooperation
69	10	♂	Grand mal Petit mal	Four to five every month.. Two to ten daily	3 years	14 months	?	Ketosis not constant but attacks at all times
70	11	♂	Grand mal Petit mal	Occasional .... Periodic	5 years	4 months	Yes	Mental changes suggestive of dementia praecox
71	12	♀	Grand mal Petit mal	One to two every month.. Three to ten daily	1 year	9 months	Yes	Attacks persisted even after addition of phenobarbital
72	13	♂	Grand mal Petit mal	One every month.......... One to two every week	2 years	1 year	Yes	Apparently little change; now on general diet, and free
73	10	♂	Grand mal Petit mal	One to two every week..... Five to ten daily	4 years	18 months	Yes	Phenobarbital added; no improvement
74	10	♀	Grand mal Petit mal	Occasional .... Three to five daily	9 months	20 months	Yes	Thyroid extract and phenobarbital also given; no benefit
75	13	♀	Grand mal Petit mal	One to two daily........... Occasional	2 years	6 months	?	Fewer spells with phenobarbital
76	13	♀	Grand mal Petit mal	One to two every month... Five to six daily	2 years	6 months	Yes	No change
77	5	♂	Grand mal Petit mal	Three to four every year... Ten to fifteen daily	1 year	5 months	Yes	Free for six weeks; phenobarbital necessary
78	9	♂	Grand mal Petit mal	One every one to three mos. Series	7 years	5 months	?	No change
79	8	♀	Grand mal Petit mal	Two every week........... Occasional	14 months	3 months	Yes	Fewer attacks, now on general diet and phenobarbital
80	10	♀	Grand mal Petit mal	Six in all.................... One every day	6 years	8 months	Yes	Attacks no fewer; possible migraine basis
81	8	♂	Grand mal Petit mal	One every night .... One to two every day	6 years	1 year	?	Phenobarbital necessary; sometimes breaks diet
82	13	♀	Grand mal Petit mal	One every night.......... . Indefinite	8 years	1 year	?	Improved; on phenobarbital and general diet last six months
83	13	♀	Grand mal Petit mal	One to five every month... Eight to ten daily	7 years	21 months	Yes	Phenobarbital added after six months; mentally retarded
84	2	♂	Grand mal Petit mal	One every three weeks...... One to two every week	1.5 years	4 months	Yes	Diet not well tolerated; not controlled now on phenobarbital
85	4	♀	Grand mal	Series every two weeks.....	3.5 months	3.5 months	Yes	Some free days at first; no change with bromides and phenobarbital
86	12	♂	Grand mal Petit mal	One to two every month .. Two every week	3 years	To date	Yes	Phenobarbital necessary
87	5	♂	Grand mal Petit mal	One daily .... One to two daily	1 year	To date	Yes	Improved at first
88	9	♂	Grand mal Petit mal	One to two every week..... One every week	10 months	10 months	?	Grew worse; off diet now

Table 5.—*Patients Improved; in Constant Ketosis*

Case	Age	Sex	Diagnosis	Frequency of Attacks	Duration	Placed on Diet	Frequency of Attacks	Comment
29	9	♂	Grand mal Petit mal	One every week............. One every three weeks..... .	5.5 years	9/15/25	One every two or three months None	
30	15	♂	Petit mal	One to two every month....	6 months	3/17/25	....	Free seven months, one attack; no report since
31	10	♀	Petit mal	Fifty daily	1.5 years	9/ 8/25	Only a few	
32	14	♂	Petit mal	Four to five daily..........	7 years	1/ 5/25	One daily......................	Some days free; better first year
33	7	♂	Grand mal	One every two weeks.......	6 years	10/21/25	One every month.............	Attacks lighter; one free period of three months
34	10	♂	Grand mal	One every two months.....	1.5 years	6/12/26	One every three months.......	Attacks lighter
35	12	♂	Grand mal	One to two daily..........	9 years	8/20/25	One every week...............	Attacks lighter; intervals longer
36	10	♀	Grand mal	One every two or three wks.	6 years	10/ 2/26	Few in series..................	Free for eight weeks
37	7	♂	Petit mal	One daily	1 year	6/ 7/26	One every six months.........	Off diet now but will return to it as soon as mother's health improves
89	8	♀	Grand mal Petit mal	One every month........... Three or four daily	2 months	4/15/26	....	Controlled with phenobarbital at first; none for five months; no attacks for two months

In another group of cases (table 7) the patients were free from attacks for from six to twelve months. Three patients may not be following the diet now, but there is no definite information that they were free from attacks for more than six, six, and seven months, respectively. Three of the others have not had attacks for eight months, one for ten months, and one for eleven months. The latter two are no longer following

---

3. Talbot, F. B.; Metcalf, K. M., and Moriarty, Margaret E.: Epilepsy: Chemical Investigations of Rational Treatment by Production of Ketosis, Am. J. Dis. Child. 33: 218-225 (Feb.) 1927.

the ketogenic diet. One is on a diet containing a high percentage of fat, the other is on practically a normal diet.

Three patients were free from attacks for more than a year (table 8). Then, when the diet was modified, attacks again appeared but resumption of the former diet controlled the attacks once more In case 28 it is practically impossible to control attacks unless the child is prevented from obtaining carbohydrates, which is rather difficult in the case of a child of 8 years with a brother and a sister on a normal diet.

TABLE 6.—*Patients Improved; Attacks Apparently Due to Breaks in Ketosis*

Case	Age	Sex	Diagnosis	Frequency of Attacks	Duration	Placed on Diet	Frequency of Attacks	Comment
38	13	♂	Grand mal	One every week	6 years	2/ 9/26	One every six weeks	Attacks lighter; off diet now because of lack of cooperation
			Petit mal	Three every week				
39	12	♀	Grand mal	One every month	Life	8/21/25	One every two months	Doing better recently
			Petit mal	One to two every week			One every month	
40	4	♀	Grand mal	One every night	3 years	9/17/25	One to two monthly	Mother careless; worse than not on diet
			Petit mal	Twenty daily			?	
41	5	♀	Petit mal	Five to seven daily.	10 months	11/ 2/25	One every month	Free for period of two to three months; all attacks due to breaks in diet
42	8	♂	Petit mal	Fifty to sixty daily	3 years	9/10/23	One to two every week	Mother careless; patient unruly
43	10	♂	Petit mal	Fifteen to twenty daily	1 year	7/17/25	Three to four daily	Free for two weeks in ketosis; mother not sure of management
44	6	♂	Grand mal	Three every month	2 years	10/22/23	....	Free four months; attack due to break in diet; off diet now; no report for one year
45	11	♂	Grand mal	One to two daily	10 months	12/16/24	One every two weeks.	Previously controlled to some extent with phenobarbital; in ketosis, free for two to three months
46	2.5	♂	Grand mal	Three every month	2 years	6/ 6/25	One to two every month	Free for six weeks once, attacks lighter
47	7	♂	Grand mal	One to fifteen every three to five months	5 years	1/27/25	Three every year	Two attacks due to break in diet; advised by home physician to discontinue diet because of lack of cooperation

TABLE 7.—*Patients Free from Attacks for Less Than a Year*

Case	Age	Sex	Diagnosis	Frequency of Attacks	Duration	Placed on Diet	Last Attack	Comment
19	9	♂	Grand mal	Two every month	1 year	8/10/25	9/29/25	Entirely free for six months; no report since
20	4	♀	Petit mal	One daily	1 year	10/ 9/25	7/13/26	Free for ten months; diet less strict now
21	10	♂	Grand mal	Three to four every month.	3.5 years	4/ 9/26	6/ 8/26	Free for eleven months; normal diet now
22	14	♀	Grand mal	Two every three months	3 months	9/ 6/26	None	Free for eight months

Eighteen patients have been free from attacks for from one to four years (table 9). Twelve of these are now on a normal diet and are free from attacks. It is, of course, possible that some of the latter may relapse as did the three patients just mentioned, but there is every likelihood that resumption of the diet would again control the attacks. These patients and those referred to in tables 7 and 8 constitute the group successfully treated long enough so that if a break comes resumption of the diet may check the attacks.

SUMMARY

Twenty-nine of ninety-one patients suffering from idiopathic epilepsy have been freed from attacks by means of the ketogenic diet. Twenty others are definitely improved, so that 54 per cent have been definitely benefited by the dietary treatment. Forty-six per cent of the patients were not benefited by treatment, although many of them were improved temporarily. The results are summarized in table 10.

Table 10.—*Summary of Cases*

Diet definitely failed	12	
Improved but not free from attacks	30	
Free from attacks while in ketosis	10	
Free for from six months to one year	8	
Free for more than one year	18	
Attacks on resuming normal diet	3	
		91
Unclassified cases		24
Cases too recent for classification		17
Cases of idiopathic epilepsy		132
Cases of symptomatic epilepsy		
Free for more than one year	2	
Improved	6	
Failure of diet	4	
		12
Cases treated with ketogenic diet		144

Experience has shown that the ketogenic diet will free 31 per cent of the patients from attacks and will definitely improve an additional 23 per cent.

STUDIES OF EXOPHTHALMIC GOITER AND THE INVOLUNTARY NERVOUS SYSTEM

XIV. RELATIONSHIP TO SEX LIFE OF THE FEMALE *

HAROLD THOMAS HYMAN, M.D.
AND
LEO KESSEL, M.D.
NEW YORK

All observers have noticed a mutual interrelationship between the critical epochs in the sex life of the female and disturbances in the thyroid gland and the involuntary nervous system. It is our purpose to record our clinical observations in this regard, following a study of more than six years in the thyroid department of the Mount Sinai Hospital.

SUMMARY OF LITERATURE ON MORPHOLOGIC AND FUNCTIONAL CHANGES IN THYROID GLAND

Alterations in the morphology of the thyroid gland have been clearly delineated by Marine.[1] He has defined the normal gland and has shown that with iodide-lack there occurs a hyperplasia associated with vascular congestion, which may lead to a visible and palpable swelling of the gland. On the administration of iodine,[2] the gland involutes and becomes colloidal. This is accompanied by a decrease in size. A colloidal gland is therefore a gland which has once been hyperplastic, and which, having received sufficient iodine, is in a resting stage. Secondary hyperplasia may occur in this colloid goiter. Cysts and adenomas, whether diffuse or localized, may also cause a visible or palpable swelling. A goiter may therefore be hyperplastic or colloidal, cystic or adenomatous, or any combinations of these.

Anatomic changes in the thyroid are not indicative of functional alterations. The normal thyroid architecture is compatible in unusual instances with exophthalmic goiter;[3] hyperplasia of the gland occurs in the simple goiter of puberty,[1] in endemic goiter,[4] in exophthalmic goiter[3] and in myxedema;[5] and it accompanies adenomas; colloid goiters are found in normal individuals, in endemic goiter, and in exophthalmic goiter;[3] adenomas may be present in normal persons,[6] in myxedema,[3] in true exophthalmic goiter,[3] and in the nonexophthalmic types of so-called toxic goiter.[7] Attempts to correlate morphology and function, while interesting, have never been warranted by the facts.

With regard to thyroid secretion, a potent substance, thyroxin,[8] has been isolated, and amply described elsewhere.[9] The secretory rate is unstudied and not understood. An almost complete lack of secretion results in the picture of myxedema. Hypersecretion is an inference as yet unsupported by physiologic experiment.[10] Perversion of secretion (dysthyroidism), is similarly unsupported by either physiologic work or biologic analogy.[11] Nothing is more striking than the disparity between the meagerness of the data and the plethora of hypotheses concerning the secretion of the thyroid gland.

Anatomic changes, particularly hyperplasia, may frequently accompany alterations in the sex life of the female. Hyperplasia may occur with estrus, pregnancy and puberty. Many unwarranted inferences have been drawn as to this association. To us, the hyperplasia means simply that associated with evidences of activity of the female sex hormone there is an iodide lack in the thyroid, which leads to hyperplasia. Inferences concerning secretory rate are unwarranted, and no widespread theory concerning glandular interrelationship has the weight of experimental or clinical fact.

PHYSIOLOGY AND PHARMACOLOGY OF THE INVOLUNTARY NERVOUS SYSTEM

The involuntary nervous system is characterized by its operation beyond or beneath consciousness,[12] and by its pharmacologic reactions.[13] Its morphology has been amply described.[14] Pharmacologically, it is subdivided into a thoracicolumbar system, which is stimulated by epinephrine (sympathomimetic); and a craniosacral system, which is *stimulated by pilocarpine* and paralyzed by atropine. The ganglions of both subdivisions are first stimulated, then paralyzed by nicotine. The subdivisions are as a rule mutually antagonistic, and frequently each system has within itself fibers mutually antagonistic to identical structures. The involuntary nervous system is in constant tonus. The factors that regulate this tonus are at present unknown. Doubtless there is some central control not yet completely worked out. The chemical theory of the regulation of tonus by the anions and cations to date has failed of complete experimental proof.[15] Its regulation by the hormones is a nebulous and popular hypothesis, opposed by experimental work. The factors that may affect the involuntary nervous system in health and disease are similarly unknown. The theory of emergency stimulation by epinephrine is much disputed and not acceptable, at least to us, on the basis of our experimental work.[16] Even the everyday observation of the association of stimulation of the involuntary nervous system by emotion is not satisfactorily worked out. Specifically with regard to the involuntary nervous system and female sex hormones, there seems to be some unquestioned interrelationship as yet unknown. Whether this is due to a common response to some underlying biologic change, whether it is purely morphologic and not functional, which system is affected first, which is causative and which effective, is at present wholly unknown, and most speculation serves merely to emphasize the ignorance of the theorist.

RELATIONSHIPS OF FEMALE SEX HORMONE

A. *The Clinical Relationship Between the Female Sex Hormone and the Thyroid Gland.*—Thyroid hyperplasia often accompanies the most important epochs in female sex life. The gland frequently undergoes hyperplasia during estrus, but as it involutes immediately, it is a matter of no concern to the clinician, except so far as reassuring an apprehensive patient is concerned. A more constant and lasting hyperplasia occurs at puberty and during pregnancy. Perhaps it would be more accurate to say that, when there is a tendency for the development of goiter, this tendency becomes more marked at the various critical epochs in the female sex life.

In our studies, about one third of the "goiter" patients developed a hyperplasia at the time of puberty. That this hyperplasia is more strictly related to the female rather than the male sex hormone is indicated by the enormous preponderance of girls and women who develop goiter, the relationship in our series at a seaport being about nine females to one male. A physiologic hyperplasia also occurs during pregnancy, and this, of course, is more apparent in a goiter belt than at a seaport; during the menopause again the same relationship is noted. When symptoms are not associated with the goiter, irrespective of whether the tumor is hyperplastic or adenomatous, iodide may be freely administered as a routine measure. Recently there has been a great furor over the dangers of iodine administration to individuals with adenomatous glands. This danger we regard as tremendously exaggerated. It occurs at most in a fractional percentage of cases, and it is a temporary phenomenon. It should not deter the physician from the routine administration of an iodide in the nonsymptomatic goiters that occur synchronous with the epochs in the female sex life. The simple salt of sodium or potassium iodide in small doses of from 2 to 5 grains (0.13 to 0.3 Gm.) once or twice a day is as good as any other measure. The tendency to use more costly organic salts is a luxury. Physical therapy and roentgen-ray and radium therapy, so commonly practiced, are a menace.

When we speak of nonsymptomatic goiter, we are discussing a condition that has almost ceased to exist for, thanks mostly to the ardent medical writers and lecturers for the lay public, and to the overzealous public health worker and life extension bulletins, practically every woman with a goiter has with it an anxiety neurosis ("goiterophobia"). Almost all our patients came to us with symptoms directly referrable to this "goiterophobia." They have a fear that is either due to a mechanical disturbance, such as choking or inability to swallow, or due to some toxic disturbance simulating exophthalmic goiter, the symptoms varying in degree and intensity almost directly with the amount that the patient has heard or read. The iodide therapy must be accompanied by reassurance, particularly that operative intervention is not and will not be necessary. The extravagances of the surgeons have also helped in no small way to further this anxiety state, one of the most zealous claiming that in his state more than three fourths of the young women have a goiter, and of this three fourths, one half have toxic symptoms. Such a statement would imply that more than 37 per cent of the young women in a goiter belt have toxic symptoms of thyroid disturbance. McCarrison and Marine and others who have worked in goiter belts have carefully noted that exophthalmic goiter is no more common in these districts, and seems not to be influenced by the presence of endemic goiter.

True exophthalmic goiter is a relatively uncommon disease. When present, the diagnosis offers little difficulty. The great error is in making the diagnosis when the disease does not exist, and in our experience this error is made with amazing frequency. Of the patients sent to our clinic with the diagnosis of exophthalmic goiter, only a very small proportion suffered from the disease. In goiter belts we are convinced that the majority of patients operated on for exophthalmic goiter and toxic adenomas do not suffer from either of those diseases as we know them. The danger of so-called iodine hyperthyroidism has created an anxiety neurosis in physicians, a state that has seriously interfered with the prophylactic and curative use of iodides. Between the fears of the patient and the fears of the physician, the whole subject has become unnecessarily complicated and obscured.

B. *Relationship Between the Female Sex Hormone and the Involuntary Nervous System.*—Disturbances of the involuntary nervous system are particularly prevalent during puberty and at the menopause. Usually the disturbance is not confined solely to the craniosacral system (vagotonic), or the thoracicolumbar system (sympathicotonic), but it is a mixture of the two (autonomic imbalance),[17] differing in each individual. The causes for the disturbance of the involuntary nervous system (autonomic imbalance), to us, at least, are unknown. These disturbances may or may not be accompanied by a morphologic change in the thyroid. We have not been able to make out a constant relationship. At puberty or the menopause, an autonomic imbalance may be present without goiter, or a goiter without autonomic imbalance, and what it is that determines which, if either, is to appear, is a matter purely

17. Kessel, Leo; and Hyman, H. T.: Autonomic Imbalance, Am. J. M. Sc. **165**: 513 (April) 1923.

for speculation. Certainly, no hormone therapy has been of any value in our hands; we use iodides for the goiter, and for the autonomic imbalance we employ a policy of "skilful neglect." Particularly at puberty, when the imbalance and the goiter coexist, a differential diagnosis must be made from true exophthalmic goiter. True exophthalmic goiter is extremely rare at this age, and is associated with a real elevation of the basal metabolic rate. The "goiterophobia" adds to the diagnostic dilemma, for the resulting emotion of fear causes an autonomic imbalance which may produce tachycardia, tremor, sweating or diarrhea, and the syndrome may then closely resemble exophthalmic goiter. Here the basal metabolic rate will determine the diagnosis, for it is elevated only in true exophthalmic goiter. A word of caution concerning the readings of the basal metabolic rate would not be amiss. Usually the first readings are erroneously high, owing to fear and lack of cooperation on the part of the patient. The word "basal" means mental and physical rest, and one should be certain in getting a reading that the metabolic rate is truly basal. At puberty, when the rate is normal, the patients should be reassured; their school work should not be interfered with; they may be permitted indulgence in all athletics, but not in competitive sports, and too earnest students should be barred from extracurricular work. Except for an avoidance of excess either in study or in sport, and the administration of iodides, we believe that the less these children are interfered with, the better it is for their general welfare. Foci of infection, particularly in the tonsils, should be eradicated.

In the simple goiters unassociated with elevation of the basal metabolic rate, we have not found constant change in the sex physiology. There is no reason why these patients should not become pregnant and bear healthy children. All pregnant women should receive doses of iodides throughout pregnancy as a prophylactic. When the thyroid is at all enlarged, the iodides should be given in larger doses, both as a curative agent for the mother and as a prophylactic for the fetus, for Marine[1] has clearly shown that the litter of a goitrous dog has thyroid hyperplasia, and that this hyperplasia may be prevented in subsequent pregnancies by the administration of iodide throughout the period of gestation.

The symptoms at the menopause we are wholly unable to cope with in any routine manner. Substitution therapy in our hands has been, with rare exceptions, a useless procedure.

Patients with autonomic imbalance stand the test of pregnancy well, and there is no reason to fear that the period of gestation will precipitate them into a crisis of exophthalmic goiter. As a matter of fact, pregnancy sometimes seems to stabilize the lability of the involuntary nervous system. The nervousness of which these persons complain is more often psychogenic than chemical in its origin.

C. *Relationship Between Exophthalmic Goiter and the Female Sex Hormone.*—True exophthalmic goiter is characterized usually by exophthalmos, goiter, tremor, tachycardia and an elevation of the basal metabolic rate. Of these symptoms the tachycardia and the elevation of the basal metabolic rate alone are constant, and a diagnosis of exophthalmic goiter should not be made in their absence. That some unknown relationship exists between exophthalmic goiter and the female sex life is a common observation. The disease is more prevalent in females by four to one. It is often precipitated at the sex epochs, and it profoundly affects female sex physiology. About 10 per cent of the patients complained of amenorrhea. This may be metabolic or toxic, as in the amenorrhea of an infection such as tuberculosis. No other constant menstrual irregularity has been noted by us. Impregnation occurs normally in the patients that we have studied. For example, in a series of fifty consecutive patients, among forty-one women, of whom twenty were married, nine women had twelve children. The number of pregnancies in this group is about the average expectancy. In all of these women the puerperium and labor were normal. The majority of the patients were delivered by Dr. C. F. Jellinghaus at the Lying-In Hospital.

The effect of the puerperium and labor on the exophthalmic goiter was usually an amelioration of the symptoms, and the test of pregnancy was well met at all times by the circulatory system. The children were normal, with the exception of one stillbirth. Lactation was similarly normal. None of the patients suffered from the toxemia of pregnancy. We mention this simply because most textbooks mention the use of thyroid extract in the treatment of the toxemia of pregnancy. The rationale of this to us is obscure. It seems based on the fallacy that the hyperplasia which usually accompanies pregnancy is indicative of a hyperthyroidism, and that this hyperthyroidism is compensatory, and hence furnishes a clue for therapy. Comment on this reasoning would seem superfluous.

Though our patients have so well met the test of pregnancy, we do not unhesitatingly advise pregnancy in patients with exophthalmic goiter. Unless the circumstances are unusual and the maternal yearning is strong, we advise our patients to practice contraception. Once pregnant, however, we do not think that a therapeutic abortion is indicated because of the exophthalmic goiter per se. Certainly, therapeutic abortion is not indicated in patients with nonsymptomatic goiters, or goiters with autonomic imbalance. On the other hand, rapid loss of weight, increasing tachycardia, nervousness and elevation of the basal metabolic rate may force the attendant to induce abortion.

Repeated mention is made in the textbooks of the mechanical difficulties due to goiter during labor, and all authors mention a single case of a woman who suffocated, presumably as a result of pressure from a goiter. We believe that mechanical disturbances due to goiter are extremely rare, and that this single instance may be better ignored than perpetuated by transcribing it from one textbook to another.

We have never seen an attack of exophthalmic goiter primarily initiated by the extra burden of gestation in patients with simple goiters of no matter what morphology, or in those with autonomic imbalance. It is a serious error to advise a therapeutic abortion in these women, with the idea of preventing an attack of exophthalmic goiter.

940 Park Avenue.

Simpler Bacteriology in Medicine.—Inasmuch as the pathogenic micro-organisms produce definite lesions in the body, and micro-organisms produce definite lesions in the body, and are only of importance because they do this, would it not be possible to classify them according to the lesions they cause, disregarding the minor variations they exhibit in morphology and biological properties? It would, of course, be a rough and ready classification, and it would break down from time to time, as all classifications do, but it would at least have the virtue of focusing our attention on the really important thing, the disease.—Kettle, E. H.: Some Aspects of Inflammation and Infection, *Lancet* **1**:1169 (June 4) 1927.

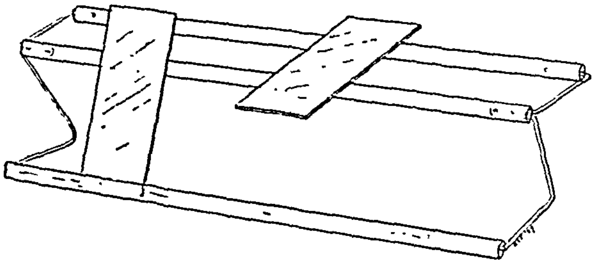
Clinical Notes, Suggestions and New Instruments

A USEFUL, SIMPLY CONSTRUCTED STAINING RACK[*]

Roy F. Feemster, M.D., D.P.H., Louisville, Ky.

It is often a problem to find a place to lay a slide when staining or drying it in a laboratory which is not provided with special staining vessels with slide rests or holders. Becoming tired of having my slides fall from improvised rests while staining them, or having to stand them against reagent bottles to dry, I was finally reduced to constructing a staining rack for my own use. It has proved so satisfactory that I deem the idea worth sharing with others.

All the materials necessary are three pieces of glass tubing of the same length, and a piece of fairly stiff wire. The wire is run through the front lower piece of tubing, as shown in the accompanying illustration, and about 8 or 9 inches is allowed to project out at each end. These ends are bent at right angles to the tubing in the same direction. About 2¼ inches back each wire is bent up and forward at an angle of about 45 degrees. A double bend inward is now placed in the portions projecting upward, so that the second tube may be held in place. A perpendicular line dropped from the second tube should strike the table about a half inch back of the lower tube. The remaining part of the wire is bent back parallel with the table and the ends turned inward about 1½ inches behind the second piece of tubing to hold the third piece of tubing.



Rack for staining and drying slides.

The two upper glass tubes now act as a support for slides in a horizontal position during staining, and the two front ones allow the slides to be placed on end for draining and drying.

The rack may be made of any length, depending on the length of the tubes used. One about 12 inches long will accommodate eight or ten slides at a time and will be long enough for most laboratories. A piece of blotting paper placed under the rack will protect the table and at the same time hasten the draining of the water from the slides.

738 East Chestnut Street.

SPLENOMEGALIA LYMPHATICA HYPERPLASTICA, OR GENERALIZED GIANT LYMPH FOLLICLE HYPERPLASIA OF LYMPH NODES AND SPLEEN

R. D. Baker, M.D., Summit, N. J.

Three cases of splenomegalia lymphatica hyperplastica have been reported by Brill, Baehr and Rosenthal.[1] My patient was a man, aged 50, who came to my office for the first time, Oct. 22, 1926, with a history of swollen nodes behind the ears and on the back of the neck since early summer. He complained also of occasional cold and hot feelings; of discomfort in the upper abdomen, irregularly; of being very tired; of slight headache and of nervousness and at times nausea. He did not sleep well and had no appetite.

The family history was negative. The personal history was negative, except for an appendectomy in 1915.

On physical examination the principal positive observations were: very bad breath; blood pressure 100 systolic and 60 diastolic; pulse 96; temperature 99.2; one dead tooth; slightly increased tone in the upper right rectus; tenderness in the region of the gallbladder; liver palpable, soft and regular; tip of the spleen palpable and tender; some enlarged glands back of each ear above the sternocleidomastoid insertions, many small cervical and a few occipital glands rather tender, and a few enlarged inguinal glands. The patient was only 5½ pounds (2.5 Kg.) under normal weight. Two successive blood counts were normal without observations of interest. The Wassermann reaction was negative.

The stomach contents showed an absence of hydrochloric acid with much mucus.

Because of the discomfort in the upper right part of the abdomen, the very bad breath, the lack of appetite, and the patient's age, a series of barium tests of the gastro-intestinal tract was done. The result was negative, except for an adhesion in the pelvic area, from which the appendix had been removed. There was no stasis.

Biliary drainage produced a massive culture of *Bacillus pyocyaneus.*

This was a lymphomatosis without changes in the blood, and with some suspicious abdominal symptoms.

Biopsy was done on one of the glands back of the ear by Dr. H. S. Martland of Newark, N. J., who reported giant lymph follicle hyperplasia. Since the case was of considerable interest, a specimen was also sent to Dr. George Baehr of New York, co-author in the original article, who agreed with Dr. Martland in the pathologic diagnosis.

Biliary drainage and duodenal lavage with hypertonic salt solution was followed for a time.

The patient was instructed to take dilute hydrochloric acid with his meals, and was given a half grain (0.03 Gm.) of neutral acriflavine three times daily after meals. Roentgen-ray treatments over the glands and spleen were begun.

One dead tooth was removed.

At present March 31, 1927, the glands, which had progressed somewhat during the working out of the case, have very much receded, the spleen is not palpable, and the patient is much improved in health. His only complaint is of easy fatigue. Cultures of *pyocyaneus* are no longer obtained from the bile. This, I believe, is the seventh case on record, the original authors having had two cases since their first article.

52 De Forest Avenue.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

B. ACIDOPHILUS MILK-FAIRCHILD.—A whole milk cultured with *B. acidophilus.* It contains not less than 50 millions of viable organisms *(B. acidophilus)* per cubic centimeter at the time of sale.

Actions and Uses.—See Lactic Acid-Producing Organisms and Preparations, New and Nonofficial Remedies, 1927, p. 216.

Dosage.—Ordinarily the contents of one bottle (200 cc.) may be taken daily—at one time, or divided as preferred. The quantity may be greatly increased by direction of the physician, especially at the beginning of the treatment when the contents of two or three bottles may be consumed daily. B. acidophilus milk-Fairchild is marketed in bottles containing 200 cc. (7 fluidounces); it must be kept in a cool place and should be used prior to the date stamped on the label.

Manufactured by Fairchild Bros. and Foster, New York. No U. S. patent or trademark.

RELATION OF CALCIUM AND BILIRUBINEMIA TO INTOXICATION WITH CARBON TETRACHLORIDE

The extensive employment of carbon tetrachloride in the treatment of persons harboring the hookworm has made it imperative to give careful consideration to the behavior of the anthelmintic substance itself in the body of the host. Tests made on experimental animals have revealed some discrepancies that were difficult to account for. In some groups of individuals enormous doses of the tetrachloride were tolerated, while others showed a considerable rate of morbidity and even of mortality as the result of a far smaller intake of the drug. These seemingly inexplicable variations appear likely now to be accounted for by the studies of Minot[1] on behalf of the International Health Board at the Vanderbilt University Medical School, Nashville, Tenn. The most consistent change found in dogs after the oral administration of carbon tetrachloride was a marked increase in the concentration of bilirubin in the blood as shown by determination of the icteric index. This constituent, which is normally present only in traces in dog's blood, began to increase about twelve hours after the dose was given, and the more severe signs of intoxication appeared soon after the bilirubinemia reached a high level.

It has been known for some time that bile pigments readily combine with calcium in the blood. This protects the organism against the toxicity of bile pigments, but at the same time depletes the reserve of calcium in the tissues and causes an increased elimination. There may be an actual increase in the total calcium present in the blood; but much of it is combined with bilirubin, so that a decreased concentration of ionized calcium results. Minot's observations indicate that the unfavorable symptoms of carbon tetrachloride intoxication appear most commonly in cases in which there has been a deficiency of calcium in the diet. Indeed, experimentally the signs of intoxication can be prevented by the continued addition of calcium to the diet, or cured either by the intravenous injection of calcium chloride or the oral administration of ammonium chloride. The latter, which produces an acidosis, represents an indirect means of raising the level of the blood calcium.

According to Minot, therefore, the immediate cause of death following the administration of carbon tetrachloride may be attributed to the lack of ionized calcium in the blood, secondary to the bilirubinemia. Fortunately, few uncomplicated human deaths from carbon tetrachloride have been reported. The fact that convulsions have been observed in some cases is in harmony with the theory of calcium deficiency, the latter occasionally leading to symptoms of tetany, particularly in children. Minot believes that the experiments indicate the advisability of an adequate calcium diet for a considerable period preceding carbon tetrachloride administration, and suggests the possibility of calcium therapy in cases of acute intoxication. The Nashville investigator has not overlooked the possibility that the production of serious symptoms by the lack of dietary calcium might occur as readily in any other jaundiced condition. This deserves serious clinical consideration.

ANTHOCYANINURIA

Unusual pigmentations of the tissues or fluids of the body are much more likely to obtrude themselves into the notice of the clinical observer than are less conspicuous abnormalities. A jaundiced skin or a bloody urine are not frequently overlooked in the examination of a patient, for they present rather striking variations from the normal appearances in healthy persons. Bilirubinemia and hematuria are symptoms of importance to the physician, for they represent the effect of disturbances in the normal function of the organism. Occasionally discolorations are observed that are due to some uncommon food or drug, and such changes may be both temporary and innocuous. If they simulate the symptoms of more serious abnormalities it becomes highly desirable to make a clear distinction between the significant and the unimportant indications of the unusual. There are drugs which, when eliminated through the kidneys, yield a urine that may simulate albuminuria in some of its reactions.

During the World War when the shortage of food necessitated the use of larger amounts of readily available vegetable foods in the central empires, cases of peculiar skin pigmentation resembling icterus were reported. These differed from the usual color symptoms of true jaundice, however, in that the offending pigment could not be identified with bile pigment. Carrots were present in the diets of all those affected, though not all who ate these vegetables freely were affected. When carrots were withdrawn from the ration the color disappeared from the skin. On the basis of such observations, Hess and Myers[1] designated the clinical picture as carotinemia. The condition was ascribed to temporary excess, in the blood, of the carotinoid pigment carotin, derived from the food. The majority of the cases involved children, although carotinemia has also been reported in adults.[2] It has been characterized by a marked orange yellow skin pigmentation, most intense in the palms of the hands, without involvement of the sclerae. The bright golden yellow blood serum has been found to contain carotin.

[1] Minot, A. S.: The Relation of Calcium to the Toxicity of Carbon Tetrachloride in Dogs, Proc. Soc. Exper. Biol. & Med. 24: 617 (March) 1927.

Poole[3] has recently called attention to a somewhat analogous condition which apparently occurs rarely; that is, pigmentation of the urine following the ingestion of red beets (*Beta vulgaris*), which might readily be mistaken for other conditions in which red pigment appears in the urine. In the instance reported by him the presence of the dye in the urine probably is the result of a change in permeability of the kidney from injury done by nephritis following an attack of scarlet fever, as it had never appeared prior to that time. As the red color of beets has been attributed to an anthocyanin pigment, the newly described symptom has been designated as anthocyaninuria. The precise identity of the pigment has, however, not yet been accurately established. The absence of blood pigment or its derivatives from the urine, and the lack of red coloration when beets are excluded from the diet, serve as a differential identification.

NORMAL BLOOD COUNTS

Clinical medicine is dependent on certain "normal" standards of comparison for assistance in the diagnosis of many disorders. Body temperature, heart rate, respiration rate, gastric acidity, urinary output and basal metabolic rate afford illustrations of some of the factors that enter into consideration here. Consequently it has become of the greatest practical importance to secure well established standards and likewise readily applicable methods of diagnostic analysis. Appreciation of digression from the normal obviously depends on recognition of what is represented by the latter state. Frequently, if not always, the "normal" is represented by a range of values rather than by any fixed figure or unvarying unit. Circumstances well within the possibilities of good health may give rise to variations within perhaps narrow yet not negligible limits. Environmental conditions, seasons, regimen, age or sex may introduce modifying factors that need to be taken into account before abnormality is postulated.

Not long ago a clinical investigator[4] wrote: "The value of color index, volume index and hemoglobin determinations in the differential diagnosis of anemias is well known. But the absence of correct normal standards for the number, volume and hemoglobin content of red cells and the inaccuracy of almost all the clinical hemoglobin methods is a great handicap." It may come as a surprise to the general practitioner to realize that the repeatedly quoted figures for the average red blood count, namely, 5,000,000 per cubic millimeter for men and 4,500,000 for women, were originally based on relatively few actual counts made seventy-five years ago. Like many data and statements of a general character, they have been handed down by repetition in textbooks without serious experimental confirmation. Of course, experience with thousands of patients has lent confidence to the acceptance of the figures quoted, even though the methods employed for their measurement by Vierordt in 1852 and Welcker in 1854 are said to be obsolete. Can it be asserted with equal assurance, as one may read in a recent guide[5] for medical examinations, that counts below 4,500,000 in the male or below 4,000,000 in the female indicate the presence of anemia, and that anything over 6,000,000 may be considered a polycythemia?

It was with the purpose of supplying better founded standards for the normal averages and determining the range of variation in normal counts that redeterminations of certain blood conditions have been undertaken at the University of Oregon Medical School,[6] on both young men and women in good health. They showed an actual average red cell count in 100 women from 18 to 30 years of age of 4.8 million, 90 per cent of the cases falling between 4.3 and 5.3 million. In contrast to this, there was an average count of 5.4 million in 137 men from 19 to 30 years of age, with 90 per cent falling between 4.7 and 6.1 million. The average total hemoglobin for each hundred cubic centimeters of blood in young women is 13.7 Gm., with 90 per cent of the results falling between 12 and 15.5 Gm. In men the average was 15.8 Gm. (not 13.8 Gm., as is commonly stated), and 90 per cent of the results fell between 14 and 18 Gm. The total volume of packed red cells per hundred cubic centimeters of blood averaged 41 cc. in women (90 per cent between 37 and 45) and 45 cc. in men (90 per cent between 40 and 50).

These studies have yielded some additional facts of an unexpected character. The red cells in women appear to be slightly, though demonstrably, larger than those of men. There are suggestions of similar differences of racial or geographic origin aside from the well known effects of altitude on the distribution of the blood cells. Diurnal and seasonal variations have been described. Obviously, these and other possibilities need far more extensive investigation before thay can enter into the precise definition of "normal" blood counts. The way has been paved for a painstaking evaluation of these.

THE VITAMIN CONTENT OF HUMAN MILK

Few foods, if any, have received more detailed consideration with respect to their chemical composition and nutritive possibilities than has milk. The variations in the proportions of the familiar constituents in the mammary secretion of different species and breeds, and likewise the alimentary behavior of the milk nutrients, have been noted, expounded and exploited until they have become part of the popular knowledge of nutrition. The propaganda for milk has made every school child familiar with its values and virtues. There are, however, certain important properties of milk that have not yet been subjected to the rigorous quantitative interpretations that are currently applied to its protein and fat. The vitamins are not yet so readily evaluated in convenient units like pints and calories. Such information as has been accumulated with respect to the A, B and C factors, and more recently the vitamins D and E, has been derived from cow's milk. Knowledge of the vitamin content of human milk, the "prototype of the perfect food," has heretofore been restricted to a few fragmentary observations. It is known that diet influences markedly the vitamin content of the milk of the dairy cow. Almost nothing is recorded about the comparable variations of the human product.

Part of the gaps in such information have lately been filled by a series of excellent studies from the Nutrition Research Laboratories of the Merrill-Palmer School and the Children's Hospital of Michigan, in Detroit.[1] The experiments of Dr. Macy and her associates there show that milk from women on the average American dietary is apparently a relatively rich source of vitamin A. Further evidence of the potency of breast milk is illustrated in the children's clinics, where xerophthalmia due to deficiency in vitamin A is rarely, if ever, observed in nursing infants.

On the other hand, the Detroit observations indicate that the antineuritic potency of mixed human milk, at least from a group of women receiving the average American dietary, is slight. It should be recalled that animal organisms are apparently utterly unable to synthesize vitamin B. In view of these facts, Macy believes it possible that many mothers do not supply enough of vitamin B to their babies. At the best, the average healthy mother is producing a milk that is exceedingly low in vitamin B, and for the economy of the mother's nutrition and to safeguard her offspring, *food materials rich in this important food component should form a prominent part in the diet of pregnant and lactating women.* Food substances rich in vitamins should be introduced early in the nursing period of the infant, whether breast fed or artificially fed.

Current Comment

THE INDEX NUMBER

In this number of The Journal appears the index to the first volume for 1927. It has been prepared with a view to making easily available to those who keep copies of The Journal all the material that has appeared during the past six months. It is thoroughly cross indexed, and the practical needs of the reader have been kept primarily in mind. A list of periodicals abstracted, appearing on pages 2055 and 2056, indicates the scope of the Current Medical Literature department of The Journal. The usefulness of a periodical, such as The Journal of the American Medical Association, is entirely dependent on the ability of the user to derive from it all that it offers. The index in this number is planned particularly to make it enduringly useful, rather than a publication of the transient character of most of the periodical literature of our time. Because of the scope of the index, some of the departments regularly appearing in The Journal have been abbreviated in this issue and others omitted.

OCCLUSION AND GASEOUS DISTENTION OF THE BOWEL

The cause of the rapidly developing serious consequences that follow acute intestinal obstruction produced in a variety of ways represents one of the perennially discussed questions of practical medicine. The necessity of prompt surgical intervention is generally recognized, and operative relief is attempted on the basis of extensive empiric experience. The observations on the genesis of the violent effects that follow complete occlusion of the bowel suggest the intervention of some highly toxic substance. A few years ago the intoxication was described by some investigators as the secondary effect of the loss of water through the commonly attendant vomiting and deficient absorption. The consequent dehydration was assumed to lead to disintegration of tissue substance, with liberation of toxic products. This view, championed by Hartwell and others, has for the most part been abandoned in favor of the hypothesis of a more direct production of harmful substances directly by bacterial changes in the occluded portions of the bowel. A contributory possibility has recently been described by Gatch, Trusler and Ayers[1] of the Indiana University School of Medicine at Indianapolis. They have demonstrated clearly by animal experiments that when the gas pressure within an occluded loop is increased there is a proportionate decrease in the rate of blood flow through it. In this way bacterial changes within the lumen may lead to anemic stasis of the blood in parts of the intestine. As the Indiana surgeons point out, one can readily surmise that, even in the absence of mesenteric strangulation, circulatory stasis and necrosis may develop in the obstructed bowel from gaseous distention alone. The rate at which this process operates will depend on the nature and location of the obstruction. In cases of simple occlusion in which incarceration of the bowel does not occur, reverse peristalsis may for a time prevent overdistention. Usually, however, they add, the complicated intestinal loops trap the gas in small pockets, and the constant gaseous formation from bacterial activity readily leads to pressure sufficient to occlude the blood supply in the manner described. They regard it as obvious, however, that this mechanism is more rapidly fatal under conditions in which a section of the bowel is incarcerated. It is only a small step further to conceive how gaseous distention by bacterial action in the strangulated loops rapidly produces gangrene and fatal absorption of toxins. Hence Gatch and his colleagues believe that necrosis of the bowel is the chief factor in making intestinal obstruction a desperate surgical emergency and that this process must be arrested early or death is inevitable.

---

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Police and Society Cooperate on Parking Problem.—The chief and the captain of police of Fresno appeared before the Fresno County Medical Society, May 3, to consider the increasingly troublesome problem of parking by physicians on the streets of Fresno. Heretofore, special privileges have been granted to physicians, and it appears these privileges have been abused by a few who obtained duplicate plates for their second car, which was used by the family; nurses, cultists and dentists to whom parking privileges was not extended also attempted to profit by the old plan. The police department, therefore, canceled the parking privileges to all physicians, May 1, and now plans to issue new distinctive insignia for physicians' cars to be selected by a committee of the county society acting in cooperation with a committee representing the police department.

Millions for Small-Salary Patients—Physicians' Services Free.—The Good Hope Hospital Association, Los Angeles, a nonprofit, nonstock organization, has a fund of more than $2,000,000 which has been invested in securities for the purpose of aiding persons earning small salaries to pay their hospital expenses when ill. Dr. Ernest A. Bryant, one of the directors, writes that the hospital has a staff "picked from the best talent in all the specialties who, of course, donate their services." For the present an agreement has been made with the Good Samaritan Hospital whereby as many rooms as the Good Hope Hospital Association needs for patients up to 100 will be provided. The hospital will collect from patients an amount which they are able to pay, and the Good Hope Hospital Association will pay the difference between that and the actual per capita cost. The association hopes to raise a still larger fund and eventually to build its own hospital. In May, Mr. Henry E. Huntington died, leaving $2,000,000 to build and endow a hospital in memory of Collis P. Huntington and Howard E. Huntington, and it may be that this fund and that of the Good Hope Hospital Association may combine their resources. The other directors of the Good Hope Hospital Association are Dr. John R. Haynes, Allan C. Balch, Michael J. Connell, Miss Myra Hershey, James W. Jameson and William B. Mathews. In connection with the Good Hope Hospital Association, Mr. Connell has organized a sanatorium for the treatment of those who may be benefited by heliotherapy. Mr. Connell furnished funds for the site, building, equipment and endowment, and a location is being sought in the mountains of southern California. The directors and trustees of the sanatorium are Mr. Connell, Mr. Balch and Dr. Bryant.

Faculty Changes at University of California.—Samuel S. Maxwell, Ph.D., professor of physiology, University of California Medical School, will retire, August 4. Dr. Maxwell, who came to the university in 1905, has been appointed professor emeritus, and will be succeeded as professor of physiology by James M. D. Olmsted, Ph.D., associate professor of physiology, University of Toronto Faculty of Medicine. Dr. Ian Maclaren Thompson, assistant professor of anatomy at McGill University Faculty of Medicine, Montreal, has been appointed associate professor of anatomy at the University of California, effective, July 1; Drs. William B. Faulkner, Jr., and Raymond J. Millzner have been appointed instructors in surgery; Dr. George C. Hensel has been made an instructor in orthopedic surgery, and Dr. Harry M. Kanner an instructor in obstetrics and gynecology. The following promotions on the faculty of the University of California Medical School have been announced. The rank after each name indicates that to which the member has been promoted:

William J. Kerr, professor of medicine.
Howard C. Naffziger, clinical professor of surgery.
Edward S. Sundstroem, associate professor of biochemistry.
Olga Bridgman, associate professor of psychology and pediatrics.
Hans Lisser, associate clinical professor of medicine.
Richard W. Harvey, associate clinical professor of neurology.
Vaclav H. Podstata, associate clinical professor of psychiatry.
Edward W. Twitchell, associate clinical professor of neurology.
Hiram E. Miller, associate clinical professor of dermatology.
Mary E. Botsford, associate clinical professor of anesthesia.
Howard E. Ruggles, associate clinical professor of roentgenology.
Irwin C. Schumacher, assistant professor of medicine.
Alfred H. Washburn, assistant professor of pediatrics.
Eva C. Reid, assistant clinical professor of psychiatry.
Laurence Taussig, assistant clinical professor of dermatology.
Montague S. Woolf, assistant clinical professor of surgery.
Herbert S. Thomson, assistant clinical professor of surgery.
Mary Kavanagh, assistant clinical professor of anesthesia.
Antonio J. Salle, M.S., instructor in bacteriology.
Stacy R. Mettier, instructor in pathology.
Thomas H. McGavack, instructor in homeopathic materia medica.
Ottiwell W. Jones, Jr., instructor in surgery.
Stanley H. Mentzer, instructor in surgery.
John C. W. Taylor, instructor in otorhinolaryngology.
Ernst Wolff, instructor in pediatrics.

The following members of the faculty have resigned:

Goodwin L. Foster, assistant professor of biochemistry.
Guy W. Clark, assistant professor of pharmacology.
Lovell Langstroct, assistant clinical professor of medicine.
Harry I. Wiel, instructor in medicine.

CONNECTICUT

Honorary Degrees Sold—Testimony at Hearings of Eclectics.—At the hearing of appeals of eleven eclectic physicians, following revocation of their licenses by the state board of health after the diploma mill investigation of 1923, testimony was presented at New Haven, June 15, indicating that Dr. Date R. Alexander, head of the Kansas City College of Medicine and Surgery, sold honorary degrees for $200 each to any one who had completed four years of study in a medical school. Those whose appeals were being heard who possessed these honorary degrees were said to be Samuel Posner, New Haven; David K. Aronson, Waterbury; James Bockman, Bridgeport; Michael M. J'Anthony, Litchfield, and William D. MacCormack and Raymond C. Prisque, Windham. The appellants who received regular degrees from this school are Samuel Slabotsky, New Haven, and James W. Bush and Julius P. Karp, Hartford. The others who appealed at this time were A. C. H. Von Sassenhofen, Bridgeport, and Aurelius R. De Janis, Waterbury. Frederick C. Waite, Ph.D., Western Reserve University School of Medicine, Cleveland, a special investigator for the state of Missouri during the diploma mill investigation, testified that, in view of the publicity attending the investigation, Dr. Alexander said that he was going to raise the price of honorary degrees; that during the term 1922-1923 this college issued fifty-nine honorary degrees and only twenty-seven regular degrees, and that neither this college nor the St. Louis College of Physicians and Surgeons had either the equipment or the faculty to teach courses in medicine adequately.

DISTRICT OF COLUMBIA

Personal.—Dr. Charles W. Richardson, Washington, a trustee of the American Medical Association, was awarded the honorary degree of doctor of science at the recent commencement of the University of Pennsylvania for "his distinguished career and contribution to knowledge"; Dr. Richardson received a similar honor from George Washington University in 1921.

Warning Against Bathing in Potomac.—Following analyses of water from the Potomac, the District health officer has issued a warning against bathing in the river in the vicinity of Washington. The report states that the water is extraordinarily high in oxygen consumed and fairly high in volatile solids. Bathers have been admonished for years to avoid these waters on account of pollution by the city.

Smallpox Outbreak Grows.—Eleven new cases of smallpox have been reported in the District of Columbia following the outbreak believed to have been introduced by members of a carnival which recently visited Washington. The total number of cases, June 18, was twenty-three and all the patients were colored. The department of health has ordered all permits to outside shows which do not have medical staffs of their own withheld until their personnel has been inspected by the department.

ILLINOIS

Personal.—Dr. William S. Keister, formerly health officer of Decatur, has taken a position as health officer of Prince George County, Maryland.——Dr. Bernard Klein, Joliet, has been appointed physician to the Will County Sanatorium, to succeed Dr. John W. Krohn, resigned.

Liquor Licenses Revoked.—The district prohibition administrator, with headquarters in Chicago, recently revoked the liquor licenses of the following for violation of the prohibition law and regulations:

Dr. John P. Benson, Joliet
Dr. Lucien E. Demke, Joliet
Dr. George E. Fosberg, Chicago
Dr. Edward J. Robinson, Chicago

Record Low Infant Mortality Rate.—The infant mortality rate of Illinois decreased 4.5 per cent in 1926 over the rate of the previous year, reaching the lowest point recorded in the state. Last year 9,297 babies under 1 year of age died, which was 524 less than the number in 1925. Most of the improvement in the rate occurred in Chicago where it was 66.6 per thousand births against 71.5 downstate. Heretofore the Chicago infant mortality rate has always been higher than the downstate rate. The average annual number of infant deaths in Illinois for the ten years prior to 1921 was 12,889; for the six years since it has been 10,087.

Chicago

Personal.—Dr. Joseph C. Springer, for many years coroner's physician of Cook County, has been appointed criminologist to Chicago and Cook County, a newly created position announced jointly by the chief of police and coroner.——Dr. William C. Masslow has been appointed health officer of Forest Park.——Dr. Olin West, general manager, American Medical Association, addressed the Physicians' Fellowship Club, 2451 Kedzie Boulevard, June 24; this was "Presidents' Night, an annual meeting in honor of physicians who have served as president of the club.——Dr. Herman N. Bundesen, city commissioner of health, received the honorary degree of doctor of science from Northwestern University, Evanston, June 21.

Archibald Church Library.—The medical library on the first floor of the Ward Memorial Building on McKinlock Campus, which has been named the Archibald Church Library of Northwestern University Medical School, was formally dedicated, June 15 in the presence of many local physicians and alumni of the school. There are more than 22,000 bound volumes in the library, and 175 medical journals. In addition to endowment provided by Dr. Archibald Church and his wife, substantial contributions have been received from Drs. Joseph B. DeLee and Arthur H. Curtis, from Augusta Elizabeth Lehmann and from the alumni association of the medical school. Collections of books have also been received, amounting to more than 2,000 bound volumes in the last two years. There are also about 10,000 unbound volumes, pamphlets and reprints.

Drs. Luckhardt and Carter Honored.—The International Anesthesia Research Society presented to Dr. Arno B. Luckhardt, professor of physiology, University of Chicago, and T. Bailey Carter, D.Sc., a scroll of recognition at Washington, D. C., May 16. The scroll, signed by the officers of the board of governors, was presented in appreciation of "meritorious research in anesthesia and analgesia, and for prolonged, untiring and resultful experimental laboratory studies of the biochemistry and pharmophysiopathology of ethylene, as well as such splendid cooperation of pure, with applied science, as enabled the surgeons, specialists and anesthetists of the Presbyterian Hospital (Chicago) to rapidly establish the clinical use of ethylene as a new and valuable routine method of anesthesia for the benefit of suffering humanity."

IOWA

Dr. Orton Resigns.—Dr. Samuel T. Orton, head of the department of psychiatry, State University of Iowa College of Medicine, Iowa City, has resigned, it is reported, and the state board of education has accepted the resignation. Dr. Orton, who has been with the medical school at Iowa City since 1919, is also director of the state psychopathic hospital; his resignation is said to be the eighth among members of the faculty of the medical school in the last few weeks.

Twin Lakes District Postgraduate Assembly.—The fifth annual assembly of the Twin Lakes District Medical Society was held at Burns' Alhambra Pavilion, Twin Lakes, Rockwell City, June 24, under the presidency of Dr. Alpheus W. Patterson, Fonda. The entrance requirements, the announcement states, were a well filled picnic basket, golf clubs and bathing costumes, and $1 for the registration fee. The speakers included Drs. Lee W. Dean, Iowa City, who spoke on "Otolaryngologic Treatment of Arthritis, Chorea, Asthma and Bronchiectasis" supplemented with lantern slides and a discussion of cases referred by members of the assembly; Dr. Clarence W Hopkins, Chicago, "Treatment of the Commoner Fractures", Dr Disraeli W. Kobak, Chicago, "Physical Therapy"; Dr. George W. Hall, Chicago, "Coincidence of Injuries and Neurologic Disorders"; Dr. Clifford G. Grulee, Chicago, a clinical discussion of anemias in children, pneumonia, constipation, enuresis and nervous states, and Dr. Everett D. Plass, Iowa City, a discussion of obstetric cases, including the technic for blood transfusion for puerperal septicemia, and other subjects relating to the practice of obstetrics. The Twin Lakes District Medical Society comprises the counties of Calhoun, Carroll, Greene, Ida, Pocahontas, Sac, Webster and Wright. The success of previous meetings, however, has attracted physicians from beyond the district.

KENTUCKY

Personal.—Dr. Henry P. Sights has been elected president of the Lions Club of Paducah.——Dr. Wilfred J. McIvor, Winnipeg, Canada, has joined the staff of the Moseley Hospital, Henderson, to succeed Dr. James P. Vye, who returned to Canada.——Dr. Oliver R. Kidd, Paducah, has been elected president of the Southwestern Kentucky Medical Association for the ensuing year, and Dr. Lee P. Molloy Paducah, secretary.——Dr. and Mrs. Henry V. Johnson entertained the members of the Scott County Medical Society, May 5, with a dinner at their home; Dr. Johnson addressed the society, June 2

Russellville Rotary 'Doctors' Day."—Nearly every physician in Logan County was a guest of the Russellville Rotary Club at the observance of the "doctors' day" program in May. Dr. William D. Haggard, Nashville, Tenn., former President of the American Medical Association, gave an address. There was group singing; some of the music had been written especially for the occasion to feature the "Medico." The physicians' wives, who are members of the local Woman's Club, served a feast of good things to eat; then a scientific program was presented at the moving picture theater, where Dr. Haggard gave an illustrated talk on "Methods of Diagnosis in Diseases of the Stomach and Gallbladder." Dr. William A. Duncan, president of the Logan County Medical Society, was in charge of the program.

LOUISIANA

Resolution—Physicians in Flood Areas Also Need Help.—A committee on health and sanitation at a meeting in Opelousas, June 6, adopted a resolution recognizing the primary importance of sanitation and hygiene in the flooded areas, and recommending, among others things, that: (1) the flooded areas be inspected and reported on before a permit is granted to return; (2) sanitary units be maintained until satisfactory sanitation is established; (3) necessary funds for the prosecution of the health campaign be included in the general estimate for rehabilitation; (4) as in most instances the physicians in the flooded areas require financial aid, they be carried on a salary or fee basis of the Red Cross for eighteen months with the provision that they answer all charitable calls in their community; (5) physicians not assigned to any one fixed area for charitable work may submit bills for their usual professional services rendered refugees; (6) losses by physicians in flooded areas be given respective consideration; (7) an appropriate number of nurses be assigned to cooperate with the medical authorities in the flooded areas.

MARYLAND

Dr. Truitt Appointed Director of New Clinic.—An appropriation of $30,000 has been made by the Commonwealth Fund, New York, to provide a mental hygiene clinic for the Mental Hygiene Society of Maryland, and an additional $23,000 will be advanced if the work is satisfactory and the support is needed. The appropriation is for two years, the additional fund being reserved for the three following years. The clinic will be established at the University of Maryland School of Medicine, Baltimore, and will be in operation in October. Dr. Ralph C. P Truitt, New York, director, department for the prevention of delinquency of the National Committee for Mental Hygiene, will be the director The president of the Maryland Mental Hygiene Society for which the new clinic will be established, is Dr Adolf Meyer, director, Henry Phipps Psychiatric Clinic, Johns Hopkins Hospital, Baltimore.

Personal.—Dr. James G. Howell, director, Relay Sanatorium, Relay, resigned, June 1, to devote his time to general practice.——Dr. Timothy A. Callahan has been appointed health officer of Harford County to succeed Dr. Walter B. Kirk, Darlington.——Dr. Walter M. Simpson, Baltimore, has accepted the position of pathologist at the Miami Valley Hospital, Dayton, Ohio.——Prof. Knight Dunlap, Ph D, Johns Hopkins University, has been granted a year's leave of absence to serve as chairman of the division of anthropology and psychology of the National Research Council in Washington, and Dr Karl Buehler of the University of Vienna will take Dr. Dunlap's place at Johns Hopkins the first half of the year, and John E. Coover, Ph.D. Stanford University, during the second half.——Dr. Hugh H. Young Johns Hopkins University School of Medicine, was guest of honor at a dinner at the Hotel Belvedere, recently, which was attended by about fifty of his former students and associates. The toastmaster was Dr. Alexander Randall, Philadelphia, and the chairman of the committee, Dr Montague L. Boyd, Atlanta.——Dr. Thomas R Pratt, Jr., Charlottesville, Va., has been appointed superintendent of the Eastern Shore Tuberculosis Sanatorium, Salisbury, to succeed Dr. Alva B. Burris, who will devote his time to private practice The supervision of the hospital, previous to June 1, was vested in a local board of directors, and since then has been shifted to the state tuberculosis commission.

MINNESOTA

Society News.—Dr. William M. James of the Herrick Clinic, Panama, gave a Mayo Foundation lecture, June 6, on "Intestinal Amebiasis in Man." The lecture was illustrated by specimens and lantern slides, the exhibit having been awarded a medal at the recent meeting of the American Medical Association in Washington. Dr. James has been in the Canal Zone since 1906.——The fifty-ninth annual meeting of the Minnesota State Medical Association will be held at Duluth, June 30-July 2.

Dr. Morton Wins Virginia Prize.—According to the bulletin of the Mayo Clinic, Dr. Charles B. Morton will be awarded the John Horsley Memorial Prize at the commencement exercises of the University of Virginia. The prize, consisting of $1,000, was established by Dr. John Shelton Horsley in 1925 in memory of his father, and is awarded every two years for the best thesis submitted on research on some problem in general surgery by a graduate of the University of Virginia. Dr. Morton's thesis was on "Findings in Experimentally Produced Ulcer: Etiologic and Therapeutic Considerations"; his work was done at the Mayo Foundation (The Journal, July 11, 1925, p. 124).

MISSISSIPPI

Physicians and the Flood.—Although most of the physicians in the delta flooded area lost their possessions and some were financially ruined, they are undaunted, cheerful and optimistic with regard to the future. All of them, our correspondent writes, worked almost day and night to protect and relieve their fellow men without thought of remuneration, and the state board of health had offers of services from physicians in the state sufficient to take care of a disaster several times the enormity of the flood. In the nine counties inundated, seventy nurses were used in relief work. The North Carolina State Board of Health furnished to the Mississippi board five sanitary inspectors; Indiana furnished three, Alabama one and one sanitary engineer. The state board distributed 252,000 cc. of typhoid vaccine between April 20 and June 1. Temporary full-time health departments have been organized for a period of sixty days in Humphries, Sunflower and Issaquena counties. With an intensive public health program during this period of immunization and general sanitation, it is possible that the citizens will at the end of that time desire to establish permanent health departments.

MISSOURI

Personal.—Dr. Jabez N. Jackson, Kansas City, President of the American Medical Association, received the honorary degree of doctor of law at the commencement exercises of the University of Missouri, June 8.——Dr. William Engelbach, St. Louis, received the honorary degree of doctor of science, June 8, from his alma mater, the Illinois College at Jacksonville, Ill.

MONTANA

State Medical Meeting.—The forty-ninth annual meeting of the Medical Association of Montana will be held at Missoula, July 13-14. under the presidency of Dr Fred F. Attix, Lewiston The meetings and exhibits will be held in the Elks Club Building; the house of delegates meets in the Florence Hotel. Every physician in the state is invited to take part in this meeting, and all papers are open to discussion. The surgical address will be delivered by Dr. Jabez N. Jackson, Kansas City, President, American Medical Association, Olof Larsell, Ph D., Dr. Noble W. Jones, Dr. Allen P. Noyes and Ben I Phillips, of the University of Oregon Medical School, Portland, will speak on "Effect of Nucleic Acid and Nucleoproteins on Normal Animals. Experimentally Produced Anemic Animals and Anemic Humans", Dr. James Tate Mason, Seattle, formerly secretary of the Section on Surgery, General and Abdominal, of the American Medical Association, will discuss "Management of Exophthalmic Goiter"; Dr. Allen R. Foss, Missoula, "Hay-Fever in Montana"; Dr Louis W. Allard, Billings, "Scientific Treatment of Infantile Paralysis"; Dr. Charles F. Coulter, Great Falls, "Diagnosis of Trachoma ; Dr. Archie L. Gleason, Great Falls, "Practical Use of Quartz Light and of Diathermy"; Dr. William F. Cogswell, Helena, "The Practicing Physician in Public Health"; Dr. Harold W. Gregg, Butte, "Nonsyphilitic Sclerosis of the Central Nervous System," and Dr Thomas A Fitzgerald, Missoula "Scarlet Fever." The Kiwanis Club will entertain the physicians at lunch, Tuesday. There will be a smoke , Tuesday evening, a luncheon with the Rotary Club, Wednesday; a sightseeing trip, Wednesday afternoon, a dance, Wednesday evening, and a "lumberjack lunch" at the Anaconda Copper Mining Company's mill at Bonner, Thursday The annual banquet will be Thursday evening The Health Association of Montana will meet, July 11 12, in Missoula, and the Montana Academy of Oto-Ophthalmology, July 12.

NEW YORK

Health at Albany.—Telegraphic returns to the U. S. Department of Commerce from sixty-five cities with a total population of about 29 million, for the week ending June 11, indicate that the highest mortality rate (20) was for Albany. The mortality rate for Albany for the corresponding week last year was 18.8, and for the group of cities, 12.5.

Poliomyelitis Cripples Under State Care.—May 1, the total number of patients who have been crippled by attacks of poliomyelitis and are now under state care amounted to 1,850, of whom 359 suffered the attack previous to 1916. Clinics for cripples were held in April in Cattaraugus, Olean, Franklinville, Saratoga, Auburn, White Plains, Oswego, Fulton and Poughkeepsie. The total attendance, the state department of health states, was 186, of whom 112 had had poliomyelitis and seventy-four showed other forms of orthopedic defects.

Mr. Eastman Donates Dental Dispensary to London.—It has been announced that Mr. George Eastman of Rochester has given $1,500,000 to establish a dental dispensary in London, England, which will be associated with the Royal Free Hospital. It probably will be much like the Rochester Dental Dispensary, Rochester, N. Y. The agreement provides that the British friends of the project raise funds to defray the running expenses of the institution. The activities of the dispensary are to be confined to a definite district in London which has a population of about 600,000, mostly poor and middle class persons.

New York City

Dermatologic Clinic Reorganized.—The New York Post-Graduate Medical School announces that its dermatologic clinic has been reorganized and equipped to teach all branches of dermatology and syphilology; it occupies eighteen rooms, and has facilities for the recent advances in diagnosis and treatment. Dr. George M. MacKee is director of the department, and there is a staff of forty members, twenty-one clinical assistants and ten technicians. Many members will be constantly engaged in research work.

Survey of Epidemic Encephalitis.—Large gifts have been provided by J. Pierpont Morgan and William H. Matheson for a world-wide survey of epidemic encephalitis. The plans have been completed, says the New York *Medical Week*, and the commission is to consist of the following:

Dr. Haven Emerson, professor of public health administration, Columbia University College of Physicians and Surgeons.

Dr. Frederick P. Gay, professor of bacteriology, Columbia University College of Physicians and Surgeons.

Dr. William H. Park, director, bureau of laboratories, New York City Health Department.

Dr. Josephine B. Neal, director of research.

Society News.—The International Medical Club gave a dinner, May 31, at the Columbia University Club in honor of Dr. Georges Portmann.——Donald B. Van Slyke, Sc.D., of the Rockefeller Institute, has been elected president of the Harvey Society for the ensuing year.——Dr. John B. Deaver, Philadelphia, was guest of honor at the dinner of Medico-Surgical Society of New York, Hotel McAlpin, May 21; he spoke on "Preventive Measures Against Gastric Ulcer and Malignancy."——The American Society of Medical History held a "balneology evening," June 9; Alfred Martin read a paper in English on "Geschichte Der Balneologie," and A. H. Appelmann, Ph.D., gave an illustrated talk on "Health Resorts of Germany."

OREGON

Personal.—Dr. Thurston W. Laraway, Veronia, has been appointed county health officer, with headquarters at Roseburg to succeed Dr. Richard F. Thompson.——Dr. Warren C. Hunter has resumed his work at the University of Oregon Medical School after the completion of a fellowship with the National Research Council in the department of pathology under Dr. Aldred S. Warthin, University of Michigan Medical School, Ann Arbor.

Roentgen-Ray Work Limited in Favor of Radio.—The council of the city of Salem adopted an ordinance, May 2, making it unlawful in that city to operate any apparatus that interferes with radio broadcasting or reception between 7 and 11 o'clock p. m. of any day, and between 11 and 12 o'clock noon on Sundays. The apparatus named includes, among others, roentgen-ray machines, violet ray machines, machines using the Tesla coil, or any machines incorporating devices producing high frequency oscillations, excepting radio stations licensed by the federal government or employed in interstate communication. The only persons excepted are practitioners licensed by the state in the regular course of the practice of their profession in emergency cases only. Persons desiring to operate such apparatus must file a written application for a permit which costs $1, and expires on the last day of each year. The city engineer is given the right to enter any premises for the purpose of inspecting apparatus coming within the term of the ordinance. Permits may be revoked for misrepresentation to an inspector or for violation of the provisions of the ordinance. The penalty imposed for violation is a fine of from $10 to $100 for the first offense, and from $50 to $250 for repeated offenses, or ten days in jail or both. The council considered the ordinance necessary for the immediate preservation of the public health, peace and safety of Salem, and therefore declared an emergency existed and the ordinance effective on the day of its passage. Salem has a population of about 20,000.

PENNSYLVANIA

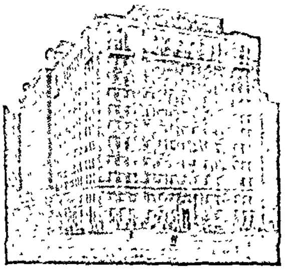
Personal.—Dr. Philip E. Marks has been appointed superintendent of the bureau of infectious diseases of the Pittsburgh Department of Health, succeeding Dr. Richard G. Burns, who was appointed city health commissioner to succeed the late Dr. Carey J. Vaux.——Mr. Frank E. Brooke, superintendent of the Harrisburg Hospital, Harrisburg, has resigned, effective, August 1.

Society News.—Dr. John S. Lundy, Mayo Clinic, Rochester, Minn., addressed the McKeesport Academy of Medicine, June 13, on "Regional Anesthesia."——Drs. John F. McCullough and James Homer McCready addressed the Allegheny County Medical Society, Pittsburgh, June 21, on "Recent Advances in the Examination of the Bronchial Tubes"; Dr. Charles Howard Marcy, "Pneumothorax in the Treatment of Nontuberculous Lung Diseases," and Dr. Forrest L. Schumacher, Pittsburgh, "Roentgen-Ray Diagnosis of Nontuberculous Lung Infections."

Philadelphia

Personal.—Dr. Herbert M. Goddard was elected president of the Physician's Square Club at the annual meeting, May 31.——Dr. James M. Anders received the degree of doctor of science at the commencement at Ursinus College, June 6.——Dr. Robert Tait McKenzie, professor of physical education and physical therapy, University of Pennsylvania School of Medicine, sailed for Scotland, June 4, to arrange for the war memorial "from his hands" that is to be erected in Edinburgh.——Dr. Ellen C. Potter, formerly state secretary of welfare, has been appointed national chairman of the campaign to raise $1,500,000 for the Woman's Medical College of Pennsylvania.——Dr. John A. Kolmer, professor of bacteriology and pathology, University of Pennsylvania Graduate School of Medicine, received the honorary degree of doctor of laws at Villanova College, July 9.——Dr. Franklin Brady has been appointed clinical professor of surgery at Temple University School of Medicine.——Dr. Ross H. Skillern was made an honorary member of the Pacific Coast Ophthalmological Society at its meeting in Spokane, June 6-7.

Proposed Building for Jefferson Medical College.—A campaign for $1,500,000 for a new medical building at Jefferson Medical College was conducted, June 6-17. The proposed building is to match the new sixteen story Jefferson Hospital, opened in 1924, with which it will be connected. It will be of yellow brick, twelve stories high, the first six floors being equipped for medical school purposes, and the remaining floors being left unfinished for future extension of the college or for conversion into hospital facilities for persons of moderate means. The present college building, erected in 1898, will be remodeled on completion of the new building for an outpatient department. Jefferson Medical College and Hospital will comprise a group of nine buildings when this structure is finished. The trustees' plan for a greater Jefferson calls for an ultimate expenditure of more than $2,000,000. There are opportunities for gifts in memory of loved ones or to perpetuate a family name by giving a laboratory, classroom or other facilities. Floor plans and a special list for memorial gifts will be furnished on request. The drive closed with subscriptions amounting to $1,513,482. Work on the new building will start at once.



GENERAL

Society News.—At the annual meeting of the Pacific Coast Oto-Ophthalmological Society, held, June 6-7, Spokane, Wash., Dr. William J. Mellinger, Santa Barbara, Calif., was elected president; Drs. Robert Hampton, Salt Lake City, and Allison T. Wanamaker, Seattle, vice presidents, and Dr. Walter F. Hoffman, Seattle, secretary-treasurer.——An International Congress on Mental Hygiene will be held in Washington, D. C., April, 1929.

May Automobile Deaths—Annual Increase 7 Per Cent.—In the four weeks ending May 21, automobile accidents caused 529 deaths in seventy-seven large cities of the United States, as compared with 493 deaths in the four weeks ending May 22, 1926. For the fifty-two week periods ending May 21, 1927, and May 22, 1926, the respective total numbers of deaths from automobile accidents in the seventy-seven cities were 6,938 and 6,348, an increase during the single year of 7 per cent.

Board to Study Montreal Typhoid Epidemic.—Surg. Gen. Hugh S. Cumming, U. S. Public Health Service, has arranged through the deputy minister of health of the Dominion of Canada for a board of officers of the public health service to visit Montreal to make an intensive survey of the typhoid situation in that city, and to secure the facts as to the source and extent of the outbreak. The board will secure such information as might be needed to enable it to submit recommendations to prevent the spread of typhoid from Montreal into the United States. The officers detailed on the board are Surgs. Leslie L. Lumsden, James P. Leake and Clifford E. Waller, and Sanitary Engineer H. R. Crohurst, all men of experience as sanitarians in the public health service.

Health Rehabilitation in Flooded Districts.—The Red Cross announced, June 16, plans for the preservation of health in areas recovering from the Mississippi flood. The expenditure of $500,000 for health and sanitation was approved by Secretary of Commerce Hoover, James L. Feiser, vice chairman of the Red Cross, and Henry M. Baker, disaster relief director of the Red Cross. There is to be, according to the announcement, a personnel of 267 health workers, including forty-five physicians, forty-nine health officers, twenty sanitarians, fifty sanitary inspectors and 103 nurses. The Red Cross plans comprise the immunization of all persons returning to the flooded areas against typhoid and smallpox, the purification of water supplies, the destruction of carcasses, the spraying of stagnant water to prevent mosquitoes, and personal nursing service. Up to June 15, when the emergency health program was practically completed, $190,000 had been spent on health work.

Institute of American Chemical Society.—An institute of chemistry will be held at Pennsylvania State College, State College, Pa., July 4-30, under the auspices of the American Chemical Society. Leaders in chemistry throughout the United States and abroad will give courses, special lectures and conferences, providing thus an unusual opportunity for contact with research workers, and for keeping in step with the progress of chemistry. Part of the program will appeal to physicians. W. Mansfield Clark of the hygienic laboratory of the U. S. Public Health Service will discuss "Oxidation and Reduction in the Living Cell"; H. C. Sherman, "General Status and Problems of Nutrition," July 27, and Dr. J. C. Drummond, University College, London, "Vitamins," July 28. Instruction will begin daily at eight in the morning; there will be at least two evening talks a week of a popular nature, and exhibits of laboratory equipment and possibly of chemical material of educational value. Fraternity buildings near the chemical laboratories on the campus will be reserved for the exclusive use of those attending the institute for $15 a week, including board. The fee for membership for the entire session will be $30. Golf, tennis, mountain drives, hiking and simply loafing with fellow chemists are among the diversions for leisure hours. The president of the college will give a garden party and reception, July 4, which the president of the American Chemical Society is expected to attend.

FOREIGN

Meeting on Disorders of Digestion.—The annual meeting of the Gesellschaft fur Verdauungs- und Stoffwechselkrankheiten will be held in the Hofburg, Vienna, October 4-7. The topics will include, among others, intestinal obstruction and ileus, diabetes, and osmosis in metabolism, and the speakers will be from Budapest, Vienna, Frankfort-on-the-Main, Berlin, Göttingen, Basel and Stockholm. The general secretary, Prof. von den Velden, Bamberger Strasse 49, Berlin W30, will give further information.

American Medical Association of Vienna.—Dr. Alfred E. Rhein, Rosedale, Ind., has been elected president of this association for 1927; Dr. Earl R. McCarthy, Chicago, vice president; Dr. Abraham I. Haskell, Minneapolis, Minn., secretary, and Dr. Herbert H. Davis, Omaha, Neb., treasurer. The association publishes a monthly journal, *Ars Medici*, which reviews and abstracts all branches of foreign medical literature. Physicians in good standing in their local organizations who visit Vienna are invited to avail themselves of the association's clubrooms, and those going abroad to study are invited to join. The purpose of the society is the systematic promotion of international postgraduate study. The April 6 meeting of the association was given over to an illustrated travelogue on Italy by Mr. Katz, formerly a student of the University of Vienna.

Postgraduate Course in Dermatology.— Under the directorship of Prof. L. M. Pautrier, a practical course in dermatology and venereology will be given at the University of Strasbourg, September 19-November 5, at the clinic for cutaneous diseases. The lectures will be illustrated by demonstrations of cases, photographs and by bacteriologic and histologic demonstrations; students will have an opportunity to apply methods of treatment and have access to the clinic outside the hours of instruction. A certificate signed by all the lecturers will be given those who complete the course. The fee is 300 francs. A laboratory course of twenty lectures and demonstrations in the general pathology of dermatoses will be given at the same time. Students may make collections of histologic slides and cultures of various ring worm parasites. Further information will be given on request to Professor Pautrier, 2 Quai St. Nicolas, Strasbourg, France.

Spahlinger Will Not Accept a Challenge

The *Daily Express* has offered to pay $50,000 toward the work of Spahlinger in connection with his treatment of tuberculosis on condition that a committee of medical experts be permitted to examine and report on it. Every effort was made to get into touch with Spahlinger, who was in London, but without success. Messages were left for him with his friends and at his hotel, but met with no response. A telegram was sent to him where he has been staying, calling his attention to the offer and requesting him to receive a representative of the *Daily Express* for the purpose of discussing his acceptance or rejection of the proposal. But an answer was not received. It was learned, however, that he was fully aware of the offer, for he was in consultation with friends concerning it. The committee proposed by the *Daily Express* consisted of Sir Thomas Horder, Dr. R. A. Young, senior consultant to the Brompton Hospital for Consumption, and Dr. Lyle Cummins, professor of tuberculosis in the University of South Wales. The terms of reference to this committee were that it was to satisfy itself that the claims made by Spahlinger present substantial hopes of a cure. In that case the *Daily Express* would contribute $50,000 to the Spahlinger Institute at Geneva for the further prosecution of the work, and would use its influence in procuring greater funds for this object. The only reply that could be evoked from Spahlinger was that he refused to be interviewed until an inordinately long and argumentative letter, which he sent to the *Daily Express* in January, was published. A reasonable summary was published—quite enough to cover the controversial points, but the letter did not contain any proof whatever that Spahlinger possessed a cure for tuberculosis.

Electrocuted While Listening In

A woman, aged 59, an expert in electrolysis, was electrocuted while listening to a wireless concert. She went to bed as usual, taking with her a book and a pair of headphones, which she connected with a receiving set. Some time later, about 10 p. m., her daughter came home and went to her bedroom, and was puzzled to notice sparks coming from the headphones near her bed. The sparks were making an unusual crackling noise. She then went to her mother's room. The room was in darkness but sparks were coming from the direction of the bed. Her mother was lying across the bed as though she had been knocked backward with some force. The daughter took the headphones off her mother's head and found that they had left marks of burns. In the mother's left hand was a small brass electric reading lamp. Her hand was severely burned and she was burned about the eyes, as though sparks had been coming from her metal spectacles as from the headphones. Some time ago when listening in she received an electric shock when she touched the reading lamp and was advised not to use it again.

At the inquest an electrical expert said that on the steel-rimmed spectacles worn by the deceased were marks of burning on the part of the frame that would normally rest near the eyes. On testing the standard lamp he found one of the flexible conductors in contact with the brass metal portion of the standard. The flex was badly twisted inside. He found a fault in the headphones arising from the fraying of the flexibles at the terminals inside the phones. The failure of these two pieces of apparatus, with the fact that the deceased was wearing steel spectacles, would provide the conditions for an electric shock. The actual circuit of the current appeared to be as follows: Live wire of the house supply—standard lamp circuit—metal portion of the standard lamp—hand—spectacles—metal portion of the headphones—wires of the wireless set—earth connection to the set. The voltage was 250 (alternating current). If the earphones had been perfect it would have been unlikely that the current would have jumped to the body of the deceased. The steel spectacles were an important factor, for their being in close contact with the skin enabled more current to pass through. The deceased suffered from a weak heart, which would account for such a low voltage proving fatal.

This is the only case recorded in this country of a fatal accident while wireless was being used. But in 1925 a young woman was struck by lightning in London while standing near the "lead-in" of a wireless aerial that was fused. Considerable damage was done to the window frame and bricks were dislodged from the wall. She suffered only from mild shock and a burn over the right hip. The earth connection was in use. It is therefore no protection against such accidents. An American accident has some interest in this connection: There has been recorded a case of electrocution while using the telephone and holding an electric lamp (*Boston M. & S. J.*, Dec. 26, 1906, p. 741). But here the lamp is not described as at fault. According to an electrical expert, the telephone and electric wires crossed at some point and were swayed together by the wind. The insulation was there burned off and a current of 3,500 volts passed into the telephone wire.

JAPAN

(From Our Regular Correspondent)

May 23, 1927.

Sex Education in Girls' High Schools

Under the auspices of the People's Marriage Guidance Society, the principals of girls' high schools of Tokyo recently met in an informal conference to discuss how the students should be instructed in sex matters and how the problem of marriage and eugenics can be dealt with in schools. In the meeting, Dr. K. Miyake, well known medical expert and director of the society, touched on the scientific side of the question. He urged that both parents and teachers possess themselves of accurate and wide knowledge regarding sex matters in order that many tragedies of marriage may be avoided. The following conclusions were reached: The society should compile textbooks containing ideas on eugenics; teachers must obtain scientific knowledge of sex; sex education must be taught in connection with ethics, domestic science, and physiology and hygiene; a course in the outlines of natural history must be taken by each student; instruction preferably should be given in groups rather than by individual tutelage.

Hospital Accommodation

According to the report from the home office, Japan has at present twenty-one state hospitals, 212 local governmental and municipal hospitals, and 7,046 private hospitals. In ordinary times, hospitals owned by the government can accommodate 4,920 patients; those owned by local governments and municipalities, 17,428; and private hospitals, 97,438. In extraordinary times, 5,166 additional patients can be accommodated by the state hospitals; 20,931 excess patients by local and municipal institutions, and 118,605 emergency patients by private hospitals.

The tuberculosis sanatorium in Tokyo contains 800 beds, while that in Osaka has 350 beds. In twelve other large cities there are 810 beds in all. Within this fiscal year four more sanatoriums with some 150 beds in all will be established.

Improvement in Prison Hygiene

Health problems in prisons have long been discussed. Dr. Akutagawa, chief of prison hygiene, returning from his inspection tour abroad, has made an increased estimate for the next fiscal year to cover the following improvements: The number of prison medical officers will be increased by forty-two; that is, to a total of ninety-eight. Prison physicians not on the official staffs will be paid more than twice as much as before. Money available for the purchase of medicines, medical supplies and instruments will be increased. Appropriations for board and clothing will be greater than before. A commission for the improvement of prison hygiene was recently organized.

A New Girls' College Attached to St. Luke's Hospital

A college for girls will be established in St. Luke's Hospital at the instance of Dr. R. B. Teusler, the chief physician. Besides teaching ordinary subjects, it will train as high class nurses and midwives girls who have graduated from girls' high schools. The expenses of the students are to be paid by the college.

Examination of Sanitary Materials

The sanitary section of the war office has commenced at the request of manufacturers and dealers to make inspections of sanitary materials and medical instruments. Instruments will be examined at the expense of those who request the examination. The following will be accepted: diagnostic instruments and syringes; tourniquets and transfusion equipment; general surgical, eye, ear, nose and throat and dental instruments; roentgen-ray apparatus; all kinds of electrotherapeutic apparatus; artificial sun lamps; microscopes; sterilization apparatus; oxygen inhalers, and clinical thermometers.

Free Distribution of Bile Medium

In order to aid in the early diagnosis of typhoid, since 1924 the metropolitan police has been distributing bile medium in ampules free to practitioners. When inoculated with the suspected material it is returned to the biologic laboratory of the bureau for examination. The plan has proved a great success. In 1924 only 1,134 ampules were used, of which 11.92 per cent proved positive. The number increased in 1925 by about 500, and in 1926, 2,571 ampules were required, of which 44.76 per cent proved positive, the total cases of typhoid being 5,743.

Personals

Prof. Dr. A. Fujinami of the Kyoto Imperial University has departed as exchange professor for South America to study sanitary conditions in Brazil.

Drs. S. Ujihara and U. Koinuma, health officers of the home office, have been made delegates, the one to the tenth Labor Conference at Geneva, the other to the Pan-Pacific Congress at Honolulu.

Dr. Yen Tshi Shang, director of the Infectious Disease Institute of Peking, China, after attending the conference of the Kyushu Medical Association as honorary president, visited Tokyo, where he was cordially received both by medical and political circles.

Mr. T. Toda of the Osaka municipal health experiment station will shortly be granted a doctor's degree in medicine (*igakuhakushi*) for his study on lice and vermin in general. He is the first man in Japan to receive a degree on the basis of this particular subject.

Dr. Y. Sata, formerly president of the Osaka Medical College, has been nominated exchange professor to Germany, and will give lectures on tuberculosis in several universities there. He also carries several reels of films produced by the education department showing ancient Japanese martial arts, it is said.

Publication of Books and Magazines in 1926

A total of 58,971 different books and magazines were published during the past year in Japan, an increase of 17,800 over the number for the corresponding period of the preceding year. Of this number, 20,313 were books and the remainder magazines and official publications. The books on medical science numbered 517, while those on physical science amounted to 231.

ITALY

(From Our Regular Correspondent)

March 15, 1927.

Gift of Library

Prof. Luigi Mangiagalli has given his large private library to the Istituto Ostetrico-Ginecologico of the University of Milan, which bears his name. The library contains, in addition to 10,000 bound volumes, a large number of unbound treatises and rare complete collections of scientific reviews.

Sanitary Regulations Introduced by the Ministerial Council

At a recent session, the ministerial council introduced several regulations pertaining to sanitary matters, for example, it was established that the lawfully recognized delegates of the medical and surgical associations shall make up the membership of the superior council on health and the provincial councils. In addition, the compensation to which health officers are entitled for work of a private nature and for laboratory analyses necessary for health control was fixed. Severe penalties were imposed for neglect to report cases of infectious disease and for fraudulent practices in connection with the manufacture and sale of food products and beverages. The advertising in the public press of preventive or curative agents that are calculated to abuse the good faith of the people is prohibited. An opportune sanitary control of abortion was established, and regulations concerning the practice of midwives and the conduct of lying-in homes were passed. Provisions pertaining to the carrying out of the law in regard to the production and sale of medical specialties were likewise approved.

A Course in Phthisiology at the Military Sanatorium in Anzio

The war ministry has decreed that a two months' course in phthisiology shall be organized at the military sanatorium in Anzio, near Rome, for the benefit of medical officers who are the heads of tuberculosis departments and who are convened at Anzio from the various army corps. Supervision of the course is entrusted to Prof. Giovanni Memmo, *generale medico ispettore* of the army medical corps (Naples). Instruction will be given by the most eminent professors of phthisiologic hygiene, among whom are Professors Maragliano, Ascoli, Sclavo and Alessandri. The primary purpose of the course, General Memmo declared, is the selection of recruits free from tuberculosis. Another object is to determine the best method of establishing the medicolegal evaluation of tuberculous lesions due to military service and the adjustment of pension claims based thereon. During the war, the army medical corps established one department for the diagnosis of tuberculosis in each army corps. In collaboration with the public health service and the Red Cross Society, climatic and sanitary centers were created for patients in the three stages of tuberculosis. From May 1, 1917, to Dec. 31, 1919, 2,202 officers and 120,392 private soldiers were examined. Of the latter, only 15,724 were adjudged fit for military service, while 53,364 were declared to be temporarily unfit and 31,731 were dismissed. The usefulness of the departments of diagnosis is apparent, for early diagnosis led to prompt removal of those found to be tuberculous and temporary removal of all suspects.

As regards the clinical forms discovered, the pulmonary type was represented by 82 per cent, in the last three months of 1918, and by 76.8 per cent, during the year 1919.

Another statistical fact of interest is the length of the interval that elapsed between the date of enrolment and the date on which the tuberculous person was eliminated. In the years 1917 and 1918, a large percentage of dismissals occurred within three months after enrolment.

After bringing out that the belief that the war had multiplied the number of cases of tuberculosis was erroneous and that the war had merely revealed those who were tuberculous or potentially tuberculous, the speaker discussed the tuberculosis mortality statistics for Italy between 1910 and 1924. The highest figures apply to the years 1917, 1918 and 1919, with 62,167, 73,944 and 62,249 deaths, respectively. The increased mortality in 1918 was due, possibly, in part, to the influenza epidemic, which aggravated many types of tuberculosis. But the mortality, after reaching a minimum of 139 per hundred thousand inhabitants in 1921, again began to rise, reaching 142 in 1923 and 159 in 1924. This observation caused Professor Memmo to remark that Professor Celli had emphasized the periodic waves that may be noted in the progress of infectious diseases, and that he himself had discovered and called attention to a decennial rhythm in the spread of typhoid in the army. In closing, the speaker stated that the sanatorium at Anzio had hospitalized thus far 3,447 patients, 3,141 of whom had been cured or improved.

BERLIN

(From Our Regular Correspondent)

May 28, 1927.

Congress of the German Society of Internal Medicine

The main paper on the second topic, "The newer methods of testing the functioning of the stomach and duodenum," was presented by Katsch of Frankfort-on-the-Main. In testing the activity of the stomach, two of the newer methods that mark distinct progress are: (1) the introduction of the retention sound, and (2) the modification of conceptions in regard to gastric acidity. Titration of the gastric contents is recommended, which is easily accomplished through the introduction of simple stimulating solutions. This procedure is based on study of the hydrochloric acid secretion of the stomach, and it was proved that the hydrochloric acid content of gastric juice varies under physiologic conditions. The variations in stimulability are utilized diagnostically in pathologic cases. The author discussed the modern method of introducing stimulating solutions as compared with the fixed conclusions as to gastric secretion based on the Riegel test meal, and emphasized the advantages of the newer method for practical diagnosis and prognosis (histamine test). Varying acidity is not pathognomonic for gastric neurosis. In general practice, the fractional test procedure as carried out with the test breakfast is sufficient for orientation. Diagnostic tests applied to the duodenum introduce refinements in the examination of the biliary apparatus. From the standpoint of method, the oil and the hypophysin experiments are in the foreground. In many cases the results are characteristic, in other cases, they are equivocal. In the diagnosis of occlusion of the gallbladder they are often helpful. Only definite results are of diagnostic value in the microscopic examination of the duodenal sediment. Leukocytosis is not an absolute proof of the existence of inflammatory processes. Duodenal diagnosis has some advantages in connection with marked obstruction of the passages of the pancreas. Occasionally, the ether pain that is elicited by the introduction of ether into the duodenum has diagnostic significance. Weil (Berlin-Neukolln) reported on experiences with the Ehrmann test beverage when only a single sample was removed by the stomach tube, and on examination of the pancreas with the Ehrmann palmitin test, both of which have been found satisfactory. Hosch of Frankfort-on-the-Main and Nonnenbruch of Frankfort-on-the-Oder discussed the osmotic concentration of the cystic bile. Bönninger of Berlin holds that the value of a test of a single sample of gallbladder contents has been overestimated and thinks that for emptying the gallbladder the administration of cream is better than the use of hypophysin. Katsch, in reply, stated that the fractioned evacuation is of value for clinical purposes and scientific study. The strongest stimulation for gallbladder evacuation is furnished by the ingestion of egg yolks.

On the fourth day a joint session with the Deutsche Roentgengesellschaft was held. Dietlen of Homburg read a paper on the importance in internal medicine of a roentgenographic examination of the lungs and mediastinum. From a clinical point of view, there is today no antagonism between roentgenologic observations and those based on a physical examination—one method merely supplements the other. A negative result may be due to improper technic or it may be the result of the physical conditions of the roentgenologic method, with which the roentgenologist must be fully acquainted. Only in a few cases, in the presence of interlobar exudates, substernal goiter or cysts, can roentgenoscopy alone decide. As a rule, the roentgenologic diagnosis must draw on clinical and anatomic observations as well.

Assmann of Leipzig discussed the normal relationships of the roentgenogram of the lung and considered the normal arterial hilum shadow in contradistinction to the shadow of the hilum lymph glands. Haenisch of Hamburg reported on the importance of roentgenologic diagnosis in disorders of the mediastinum and the lung. There is as yet no uniform technic for the preparation of roentgenograms. The operator should see that the delineation of details is as complete as possible up to the margins of the lung fields. For that purpose a small center of concentration and a wide focal distance are imperative. The advantages of the Grödel technic are unquestionable. Lorey of Hamburg presented numerous roentgenograms illustrating the use of iodized oil as contrast mediums. The iodized oil may either be injected or swallowed after anesthetization of the larynx. In spite of careful localization, one does not always succeed in getting the iodized oil to the place where it is needed. The author has found that the best method is to introduce the oil into the desired bronchial branch by means of a tube, while fluoroscopy of the region in question is done. The bronchial mucosa does not resist the presence of the oil and it may be left there for months. It is used chiefly for the diagnosis of bronchiectasis. There are many different characteristic roentgenograms when iodized oil is used as a contrast medium. It is not so useful for the filling of tuberculous cavities, as there is a danger of bacilli being transferred from one point to another. Fleischner of Vienna discussed the roentgenologic diagnosis of interlobar and marginal lobar processes. It presupposes a clear conception of space relationships, and requires fluoroscopic examination from various angles and with different movements of the patient. In addition to the usual angles of projection applied to the erect patient, the examination in lordosis posture is important. Interlobar adhesions present the same appearance as recent fibrous pleuritis, resembling striated bands. Interlobar effusions appear as bands or spindles with sharp demarcation on both sides. If the shadow is sharply demarcated on only one side, the diagnosis of an interlobar process remains uncertain. Such shadows are found also associated with croupous and influenzal pneumonia, and with abscess, gangrene or infarct. The largest number of such roentgenograms with marginal thickening are found associated with tertiary bronchogenic tuberculosis. Infiltrates with limits corresponding to the borders of the lobes are an important sign by which to distinguish these from other forms of pulmonary tuberculosis.

(To be continued)

Marriages

ALEXANDER W. CAVINS, Hartford, Conn., to Miss Grace Lillian Erickson of New Britain, April 23.

CHRISTIAN JACOB ROHWER, New York, to Miss Cornette Fisk of Spokane, Wash., May 12.

CLARK HOMER HALL, Oklahoma City, to Miss Susanmary Roberts of Nevada, Mo., June 9.

WILLIAM B. S. THOMAS, Bellingham, Wash., to DR. RUTH BORING of New York, April 12.

ADOLPH ANDERSEN, Brooklyn, to Mrs. Ethel Crumit of Sound Beach, Conn., May 27.

ROY E. GOLDNER, Lansing, Mich., to Miss Delia Eleanore Byron of Holland, May 14.

MARK G. GATES, Santa Monica, Calif., to Miss Sara Laabs of Echo, Minn., April 17.

ELEY EBERT PERISHO, Streator, Ill., to Mrs. Stella Crumrine of Geneseo, April 29.

WOODHULL LEE CONDICT to Miss B. Lyman Fonda, both of New York, June 6.

Deaths

Philip Butler Newcomb ⊕ Tucson, Ariz.; Washington University School of Medicine, St. Louis, 1901; member of the Society of American Bacteriologists and the American Society of Clinical Pathologists; secretary of the Pima County Medical Society; at various times on the staffs of state hospitals in Pennsylvania, Kansas, Maine and Arizona; pathologist to the Arizona Hospital and Sanatorium and St. Mary's Hospital; attending specialist in clinical pathology to the U. S. Veterans' Hospital, number 51; aged 47; died, April 21.

Frank Woodbury, Philadelphia; Jefferson Medical College, Philadelphia, 1873; formerly professor of materia medica, therapeutics and clinical medicine, Medico-Chirurgical College of Philadelphia, and second vice president of the American Medical Association, 1888-1889; at one time on the staffs of the Medico-Chirurgical Hospital and the Lankenau Hospital; in 1910 was secretary of the Commission on Lunacy of the State Board of Charities; aged 78; died, May 24, of cerebral hemorrhage.

Fred De Forest Bailey ⊕ Brooklyn; Medical Department of the University of the City of New York, 1882; member of the American Ophthalmological Society; consulting surgeon to the Brooklyn Eye and Ear, St. Catherine's and St. Mary's hospitals, the Baptist Home, and the Industrial Home of the Blind; aged 66; died, May 27, of heart disease.

Karl A. Emmerling ⊕ Pittsburgh; Jefferson Medical College of Philadelphia, 1890; on the staff of the Pittsburgh Hospital and formerly on the staffs of the Western Pennsylvania Hospital and St. Francis Hospital; served during the Spanish-American and World wars; aged 59; died, May 6, of pneumonia.

Joseph Schneider ⊕ Milwaukee; University of Wurzburg, Germany, 1874; specialized in ophthalmology; on the staff of St. Joseph's Hospital; served in the Franco-Prussian War; delegate to the International Medical Congress, Berlin, 1890; aged 80; died, June 4, of carcinoma of the prostate.

Joseph Hughes Shaw ⊕ Santa Rosa, Calif.; Medical College of Ohio, Cincinnati, 1908; superintendent of the Sonoma County Hospital, 1914-1918, and since 1924 on the staff of the General Hospital; aged 45; died, May 23, of injuries received in an automobile accident.

J. F. Tancredum Dubois, Buffalo, N. Y.; University of Montreal Medical Faculty, Montreal, Que., Canada; member of the Medical Society of the State of New York; formerly on the staff of the Oswego (N. Y.) Hospital; aged 73; died, May 18, of angina pectoris.

Winfield Scott Harpole, Chicago; Northwestern University Medical School, Chicago, 1897; formerly assistant professor of clinical medicine at his alma mater; at one time on the staff of the Cook County Hospital; aged 61; died suddenly, May 27, of heart disease.

Frank Carpenter Moulding, Watertown, Wis.; University of Michigan Medical School, Ann Arbor, 1876; Medical Department of Columbia College, New York, 1877; Spanish-

American War veteran; aged 73, died, May 11, at St Mary's Hospital, of carcinoma.

Frank L. Henderson, St Louis, Missouri Medical College, St Louis, 1888, member of the Missouri State Medical Association; past president of the St Louis Medical Society, aged 62, died, May 13, at his summer home in Stonington, Conn., of heart disease.

Garry de Neuville Hough, Vineyard Haven, Mass., Bellevue Hospital Medical College, 1884, member of the Massachusetts Medical Society; on the staff of St Luke's Hospital, New Bedford, 1886-1921, aged 66, died, June 1, following a long illness.

George Monroe Horton ⊕ Seattle; Bellevue Hospital Medical College, New York, 1890, past president of the King County Medical Society; formerly county coroner, aged 61, died, May 6, following an operation for adenofibroma of the prostate.

Allan Hubert Galloway, Jr., Laneville, Texas, Fort Worth School of Medicine, 1906, Medical Department University of Louisiana, New Orleans, 1909, member of the State Medical Association of Texas, aged 50, was shot and killed, recently.

Merrill Washington Hill, Redlands, Calif.; Hahnemann Medical College of Philadelphia, 1871, member of the California Medical Association, aged 77, died, May 30, at the Lane Hospital, San Francisco, of carcinoma of the colon.

H. Irvin Woodhead ⊕ Bradford, Pa., Jefferson Medical College of Philadelphia, 1896, formerly president of the school board of Forksville and coroner of Sullivan County, aged 61, died, May 23, of cerebral hemorrhage.

Leslie C. Brock, Smithfield, Va., Medical College of Virginia, Richmond, 1894, member of the Medical Society of Virginia, for twenty-two years mayor of Smithfield, aged 54, died, May 24, of cerebral hemorrhage.

Birna Richie Smith, Connersville, Ind., University of Louisville (Ky.) School of Medicine, 1903, member of the Indiana State Medical Association, aged 54, died suddenly, May 30, at Milroy, of heart disease.

Walter Joseph Otis, New York, Harvard University School of Medicine, Boston, 1880, member of the Massachusetts Medical Society; aged 73, died, June 13, at St Luke's Hospital, Chicago, of heart disease.

John Thomas Foster, Ashley, Ill.; Rush Medical College, Chicago, 1868, formerly a druggist and postmaster of Dubois, aged 86; died, May 17, of arteriosclerosis, chronic myocarditis and chronic nephritis.

Simeon S Martin, Georgetown, Texas, Baylor University College of Medicine, Dallas, 1902, member of the State Medical Association of Texas, aged 60, died, April 30, of cerebral hemorrhage.

Frank Michael MacKnight, Binghamton, N. Y.; Long Island College Hospital, Brooklyn, 1897, aged 54, died, April 30, as the result of cerebral hemorrhage, suffered some months ago.

Anton T Nadig ⊕ Elizabeth, Ill. University of Illinois College of Medicine, Chicago, 1902, aged 57, died May 24 at a hospital in Rockford, of burns received when his home caught fire.

Henry Melvin Forman, Bradford, Ohio, Miami Medical College, Cincinnati, 1880, for nineteen years president of the board of education, aged 72, died in May, of paralysis.

Edwin Myley Schindel, Hagerstown, Md., University of Maryland School of Medicine, Baltimore, 1883, formerly mayor of Hagerstown, aged 72, died, May 7.

James F. Dunn, Burleson, Texas, University of Tennessee College of Medicine, Memphis, 1886, aged 75, died suddenly, May 7, of heart disease.

James Adams Ollerton ⊕ Mesa, Ariz., University of California Medical School, San Francisco, 1925, aged 41, died, March 9, of typhoid.

John Barnett, New Haven, Ill., Barnes Medical College, St Louis, 1898, aged 60, died, May 18, of cerebral hemorrhage.

Sarah E Dunlap, Villa Park, Ill., Hahnemann Medical College and Hospital, Chicago, 1885, aged 79, died, May 7, of senility.

Ferdinand Lommen, Detroit, Catholic University, Louvain, Belgium, 1890, aged 64, died, April 18, of heart disease.

Frank C. Hamilton, Hudson, Ind., Fort Wayne College of Medicine, 1888, aged 80, died, June 1, of gastric ulcer.

Dudley A. Hadley ⊕ Oconomowoc, Wis., Chicago Medical College, 1881, aged 70, died, May 4, of heart disease.

Correspondence

THE IDEAL ANTACID

To the Editor:—In their article in The Journal, May 14, p. 1557, Drs. Loevenhart and Crandall point out the advantage of calcium carbonate in gastric hyperacidity, and conclude that it is the "ideal antacid." In this connection, would it not be appropriate to point out that other neutral antacids, not mentioned in this article, have already been the subject of not a little clinical and laboratory investigation?

All the advantages claimed for calcium carbonate have likewise been claimed for the neutral tribasic phosphates of magnesium and calcium. First "reintroduced" into clinical medicine by Greenwald, these salts have been studied independently by Shattuck and by me. The results were published in The Journal in 1923 and 1924. Since that time, the phosphates have had their share of the usual commercial exploitation.

Perhaps a comparative study of the relative values of all the neutral antacids, including calcium carbonate, might next be in order. It is possible that the clinical value of the several drugs in this group would prove to be about equal. My own impression is that although there is a limited field of usefulness for the neutral antacids, they are not sufficiently powerful to displace entirely the alkaline salts in the great majority of cases during the period of active symptoms.

John L. Kantor, M.D., New York.

TAPEWORM INFESTATION

To the Editor:—The article by Magath and Brown on the "Standardized Method of Treating Tapeworm Infestations" (The Journal, May 14) prompts me to give a method I have used for some time.

The preparation of the patient and the search for the head are practically the same as their method, but in administering the drugs I first pass a duodenal tube. When the bulb has left the stomach I inject through the tube an emulsion of 1 cc. of chloroform and 4 cc. of oleoresin of aspidium in 30 cc. of mucilage of acacia. The tube is left in place, and in about an hour the emulsion is followed by a magnesium sulphate solution. The patient does not experience nausea or untoward effects, and the worm is passed in about an hour.

I do not know that this is original, but I have never failed to obtain the head by this method.

P. S. Kaadt, M.D., Portland, Ore.

DIABETES AND MYELOGENOUS LEUKEMIA

To the Editor:—The article in The Journal (May 21, p. 1626) on the concomitance of diabetes mellitus and myelogenous leukemia is highly interesting, because of the probability of there being more than a concomitance between the two conditions. We know that polymorphonuclear leukocytes contain an enzyme similar in its action to trypsin. The inhibitory effect of trypsin on insulin in human plasma is likewise a familiar phenomenon. The fact that in some of the cases diabetes was found to have existed a variable time prior to the apparent onset of leukemia does not rule out a causal relationship between the two. Although a preleukemic or an occult leukemic period must and, in all probability, does exist, we know nothing about its duration or its manifestations. Further work on this subject might prove more than interesting.

Alexander A. Stone, M.D., Brooklyn.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed Every letter must contain the writer's name and address, but these will be omitted, on request.

EFFECTS OF KEROSENE ON SCALP

To the Editor —Please state the effect of kerosene on the human scalp. Would absorbing of the hydrocarbon cause paresis? What would be the effect on the chemical arrangement in allowing kerosene to stand exposed to the air? Would it cause any disturbance to the hair follicle or oil gland?

Roy L. Smith, Tulsa, Okla.

Answer —Kerosene is a weak antiseptic and parasiticide and irritant to the skin Therefore It can be used for parasitic affections of the scalp It is of some use for seborrheic dermatitis of the scalp and, if it has any effect in preventing the outfall of hair, it is presumably due to its irritating—stimulating—effect on the skin. But it does all these things in a crude, disagreeable way All of them can be done more efficiently and much more accurately with drugs of definite composition. Its vogue as a hair tonic and hair restorer is largely due to that popular feeling, which has come down through the millenniums from our barbarous ancestors, that the efficiency of drugs is in proportion to their disagreeableness.

The absorption of hydrocarbons through the unbroken skin would be practically nil, and even if it were absorbed to some extent from kerosene it is a new idea that they might cause paresis, it is just as reasonable an assumption that they might cause rabies Any oil or fat if used to excess on the skin has a tendency to produce folliculitis That is the only effect it would have on the oil glands

DENTAL BLOCK ANESTHESIA

To the Editor —Recently a woman came in with gingival cavities in the lower left bicuspids They were so sensitive that I gave a block anesthesia at the mental foramen Although the signs of anesthesia were perfect, it had no effect on the teeth Could this be psychologic on the patient's part? If not, will you kindly advise me how to treat these teeth so that I can fill them Kindly omit my name

D D S, Cincinnati

Answer —In giving the block anesthesia in the case quoted, only the outer fibers were anesthetized, giving symptoms of complete anesthesia The solution was not deposited close enough to the foramina to anesthetize the fibers that supply the nerves to the teeth

CARE OF THE SCALP

To the Editor —1. Will you inform me concerning Fels Naptha soap? Does it contain alkali or other ingredients that might be injurious in washing the scalp? 2 Is it healthful for the scalp to wash often, say once a week? 3 Is it healthful not to wash the scalp with soap, to use olive oil instead or what oil would be better for this purpose? 4 Is infra-red treatment considered of value in stimulating growth of the hair? Please use initials

V. R. V, M D, Kansas

Answer —1. Fels Naptha is a laundry soap It contains some alkali, as do other laundry soaps; but not enough to injure a normal scalp, which is tougher than the glabrous skin.

2 The frequency with which the scalp should be washed depends on the greasiness of the hair and the amount of dirt it accumulates. Ordinarily, once in two weeks is often enough; but under some circumstances once a week would be the proper interval.

3 Applying olive oil or other oil to the scalp cannot be compared with washing with soap It does not remove dirt, and therefore is not healthful except in the case of pathologically sensitive scalps, to which soap would be an irritant.

4 The heat that is applied by means of infra-red rays would have a tendency to dilate superficial blood vessels. Theoretically, the improved blood supply might stimulate the growth of hair provided the hair follicles had not become atrophic If the follicles had become atrophic, it is unlikely that anything would avail.

COMING EXAMINATIONS

Alabama: Montgomery, July 12-15. Chairman, Dr. S. W. Welch, Montgomery

Colorado: Denver, July 5. Sec., Dr. David A. Strickler, 1011 Republic Bldg, Denver

Connecticut: Hartford, July 12-13. Sec, Dr. Robert L. Rowley, 79 Elm Street, Hartford

District of Columbia: July 12 Sec, Dr. Edgar P. Copeland, Suite 110, 1801 Eye Street, Washington.

Hawaii Honolulu, July 11-14. Sec., Dr. James A. Morgan, Young Bldg, Honolulu

Maine: Bangor, July 5 6. Sec, Dr. Adam P. Leighton, Jr, 192 State Street, Portland

Massachusetts: Boston, July 12 14. Sec, Dr. Frank M. Vaughan, 144 State House, Boston

Missouri St. Louis, July 13-15. Sec., Dr. James Stewart, Jefferson City.

North Dakota: Grand Forks, July 5 8. Sec, Dr. G M. Williamson, Grand Forks

Oregon Portland, July 5 7. Sec, Dr. M. K. Hall, 816 Pittock Block, Portland.

Pennsylvania: Philadelphia and Pittsburgh, July 5 9. Dir. Professional Education Bureau, Mr. C. D. Koch, Harrisburg.

Rhode Island: Providence, July 7. Sec, Dr. B. U. Richards, Providence

South Dakota. Huron, July 19. Dir. Medical Licensure, Dr. H. R. Kenaston, Bonesteel.

Washington: Seattle, July 11. Basic Science Examination, Seattle, July 7 8 Ass't Director, Mr George L Berger, Olympia.

West Virginia Martinsburg, July 26. Commissioner, Dr. W. T. Henshaw, Charleston.

Indiana January Examination

Dr. E. M. Shanklin, secretary of the Indiana Board of Medical Registration and Examination, reports the written examination held at Indianapolis, Jan. 11-13, 1927. The examination covered 15 subjects and included 100 questions. An average of 75 per cent was required to pass. Of the 5 candidates examined, 3 passed and 2 failed. Seven candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent
University of Illinois College of Medicine		(1927)*	92
Indiana University School of Medicine		(1926)	87
Dalhousie University Faculty of Medicine		(1926)	87

College	FAILED	Year Grad.	Per Cent
University of Wurzburg Germany		(1925)	67
National University of Athens, Greece		(1923)†	30

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Illinois College of Medicine		(1910)	Illinois

Questionable Examination of Injured Person

(Grimes v. Thompson (Ky.), 289 S. W. R. 290)

The Court of Appeals of Kentucky says that in this action to recover for personal injuries complaint was made of the competence of the evidence of a physician who, at the instance of the defendant or his counsel, went to the plaintiff's home and made a physical examination of her to ascertain the nature and extent of her injuries, when neither the counsel nor the physician of the plaintiff was present. The ethics of such a procedure may sometimes well be called in question, but the evidence showed here that there was no objection on the part of the plaintiff to submit to such examination by the physician, that he remained at her home some two hours or more, making such examination by her acquiescence, and that she had ample time and opportunity, if she had so desired, to have notified her own counsel of such examination, or her own physician, to the end that they might have been present. Under the facts in evidence, the court does not regard this question as serious, especially as it bore on the nature and extent of the injuries, and the jury found for the defendant on the question of liability.

Validity of Will of Sufferer from Insane Delusions

(In re Ayer's Estate (Neb.), 211 N. W. R. 205)

The Supreme Court of Nebraska holds that in a proceeding to probate a will, in which the only question relates to the competence of the testator, and in which it appears that he is not generally insane but suffers from insane delusions with respect to a particular subject, the question for determination is whether he was the subject of such a delusion as controlled or influenced his action in making the will. A testator who is not generally insane but who suffers from insane delusions is competent to make a valid will, provided the insane delusions from which he is suffering do not control or influence his action in making the will. In this case the jury was instructed that if it found from a consideration of all the evidence that the testator suffered from delusions concerning his only son which rendered him insensible to the ties of blood and kindred between him and his son, it should find for the son as contestant of the will. The giving of the instruction was prejudicial to the proponent of the will, as it directed the jury to find for the contestant if the testator had suffered from delusions as therein described, regardless of the fact that such delusions might not have existed at the time of the making of the will, and regardless of whether or not they controlled or influenced the testator's action in making the will. By the instruction the mere fact that the testator may have at some time suffered from delusions such as described in the instruction would be sufficient to set aside the will. Such is not the law as this court understands it.

Society Proceedings

COMING MEETINGS

American Ophthalmological Society, Quebec, Canada, June 27-29. Dr. Emory Hill, Professional Building, Richmond, Va., Secretary.
Minnesota State Medical Association, Duluth, June 30-July 2. Dr. E. A. Meyerding, 11 West Summit Avenue, St. Paul, Secretary.
Montana, Medical Association of, Missoula, July 13-14. Dr. E. G. Balsam, 222 Hart-Albin Building, Billings, Secretary.
Pacific Northwest Medical Association, Boise, Idaho, June 27-29. Dr. Frederick Epplen, 422 Paulsen Building, Spokane, Wash., Secretary.

ASSOCIATION OF AMERICAN PHYSICIANS

Forty-Second Annual Meeting, held at Atlantic City, N. J., May 3 and 4, 1927

(Continued from page 1991)

Rôle of Thebesian Vessels in Circulation of Heart

Dr. Joseph T. Wearn, Madison, Wis.: Our experiments show that from 70 to 90 per cent of the coronary flow escapes directly into the ventricles and very little directly into the veins. When the perfusate is stained with india ink, it is shown escaping from the thebesian vessels through the walls of the heart. The chamber became greatly dilated but no fluid passed through the capillaries. If the walls did not dilate, the outflow might be different. In perfusion experiments on the human heart two hours post mortem, oxygen and the Locke-Rosenheim solution, with a little epinephrine, being used, a normal beat was obtained. The heart was then injected with dye and we found that, if the chambers do not dilate, the outflow through the thebesian vessels is lower, the flow going out through the veins better. We also injected the heart with celloidin colored blue, and a small plug came out at the end of each thebesian vessel. We have also made sections and found the veins emptying into the thebesian vessels. Therefore we may consider that the thebesian vessels can carry on the circulation when other vessels are occluded. Clinical cases have shown that the thebesian vessels can, in an emergency, supply blood to the organism.

Incidence of Syphilitic Infection in the Negro, and Disabilities It Produces

Dr. James E. Paullin, Atlanta, Ga.: In the last five years, with 4,876 admissions to the adult wards, 662 patients, or 13.8 per cent, had syphilitic infection. The reasons for seeking hospitalization have been involvement of the central nervous system or of the cardiovascular system. Of the 662 patients, 357 had either cardiovascular lesions or central nervous system involvement. The patients with involvement of the central nervous system showed various types of irritation: meningitis, plegias, headaches, convulsions. The cardiovascular group numbered ninety-eight, of which 79 per cent of cases occurred before 50. The aortic cases in negroes were due to cardiac failure. In forty-six persons, aneurysm occurred before 50. The negro is apt to acquire syphilitic infection very early in life. There were two early cases of aortitis, one at 17 and the other at 22. Arteriosclerosis with hypertrophy occurred in fifty-eight cases. The mortality was very high in all these cases. The patients come to the hospital so late that no treatment is of any avail. As to the causes of heart disease, the rheumatic incidence is very low, 8.3 per cent. The syphilitic group is as high as 39.3 per cent. Syphilitic heart disease forms 20 per cent of the adult admissions among negroes. Death often occurs before 50. Eighty-seven per cent of the patients have had no treatment for the primary lesion, and the remainder very inadequate treatment.

DISCUSSION ON PAPERS OF DRS. BROOKS, SCOTT AND PAULLIN

Dr. W. S. Thayer, Baltimore: In regard to the cases cited by Dr. Scott, one man had rupture of the valve occurring at the commissure. This is not a common occurrence. Dilatation of the ring as a cause of aortic insufficiency is a relatively unimportant point. I have not seen instances in which dilatation of the aortic ring alone was the cause. There was a lengthening of the commissure or deformity of the valve not due to syphilis. One point mentioned by Dr. Paullin I should like to comment on: patients entering with these lesions are more or less permanently hospitalized, owing to their syphilis; they are not in shape to take up active work again.

Dr. F. T. Lord, Boston: Regarding the incidence of syphilis in the etiology of angina, in 4,000 cases there were 140 cases of angina, about 4.28 per cent. Aortic regurgitation is important as an indication of the presence of syphilis in angina. Four patients out of five had aortic regurgitation. Syphilis is therefore important in the etiology of aortic lesions. I endorse Dr. Brooks' statements regarding energetic treatment in cases of angina with syphilis.

Dr. Joseph L. Miller, Chicago: I was interested to hear that the angina in syphilis appears at about the same age as the angina from other causes. When I see a man between 40 and 50 without hypertension and without a rheumatic lesion, I suspect that he has had syphilis. Many times it is true. What percentage of Dr. Brooks' cases were noted in which the Wassermann reaction was negative? In Chicago these cases are common among colored people. In syphilis of the aorta, in which the diagnosis was made early, 25 per cent of the cases showed a negative Wassermann reaction. With repeated testing they were still negative, but the autopsies showed evidence of active syphilis.

Dr. R. W. Scott, Cleveland: In these studies we must take into account the social status of the patient. In seventy-five cases, the anginal attacks were very rare. In cases of angina, at autopsy the coronary arteries were found contracted. Of our patients, 50 per cent were negroes. The white people were usually hospital patients.

Dr. Warfield T. Longcope, Baltimore: Has Dr. Paullin collected any figures as to the occurrence of pain? Pain is relatively rare in syphilitic aortitis in the negro, whereas it is fairly common in the white person. I think that in estimating the importance of syphilitic aortitis we must take into account the question of racial differences.

Dr. E. S. Kilgore, San Francisco: Cases recognized earlier are more hopeful; and it behooves us to watch particularly for early signs. Of these, in my opinion, the most valuable single bit of evidence is the roentgen-ray appearance of enlargement of the first portion of the aortic arch.

Dr. M. C. Pincoffs, Baltimore: At the University Hospital in Baltimore we have recently collected some statistics on our cases of cardiovascular syphilis. Our conclusions differ somewhat from those of Dr. Brooks. The average age of patients with cardiovascular syphilis showing anginal symptoms was 40.6 years. This average was obtained from seventeen cases. In contrast with this we found that the average age of patients with nonsyphilitic angina in the same hospital was 60 years. I believe that this difference in age incidence has a diagnostic value. We have found the prognosis decidedly worse in our cases of syphilitic angina than in those of nonsyphilitic origin. Ten of our seventeen patients are dead, with an average duration of life of only 7.3 months after the onset of anginal symptoms. In ten autopsies in cases of syphilitic angina, six showed definite occlusive changes at the orifices of the coronaries.

Dr. W. W. Hamburger, Chicago: Experience in the hospitals in Chicago is comparable with Dr. Paullin's as regards percentages in white and in colored people and also the results gained by treatment of the syphilis.

Dr. Lewis A. Conner, New York: All the evidence with which I am familiar points to the fact that when there is well developed cardiovascular syphilis with aortic insufficiency the time for treatment is long past. Real harm can result from vigorous treatment at that stage.

Dr. A. S. Warthin, Ann Arbor, Mich.: What is true in the negro is true in the white man, too. I agree with Dr. Scott that syphilis is not a disease of the vasa vasorum; it begins at the adventitia and extends to the intima and then the media, which becomes involved by slow infarction. I have never seen cases of aortitis without myocardial involvement. In a case of malignant syphilis in a man, aged 24, who had literally hundreds of sloughing lesions, treatment for four weeks was without avail. He died and the case came to autopsy. I was struck by the picture of the skin lesions. There was infarction due to obliteration of the vasa vasorum of the skin. There was involvement of the corium. The heart lesions showed obliteration of the smaller arteries, not infarction. To the naked eye there was no involvement of the aorta. There were a few pale spots on the heart muscle but no actual involvement in the gross, but the whole myocardium was involved. In the adventitia of the aorta there were early lesions, but the most marked change was a severe myocarditis.

Dr. Harlow Brooks, New York: I am not pessimistic about the treatment of syphilitic myocarditis. In New York there is a large negro population which gives the same percentages. In answer to Dr. Miller, a high percentage showed negative Wassermann reactions. Few patients, except those in private practice, had had treatment of long continuance. The average hospital patients have been treated very poorly. They *only* want to come back *frequently* to take treatment until compensation has been effected. Then they do not want to take the trouble. The usual etiologic factors of angina were present in all my cases. I find it rare among negroes. Dr. Thayer spoke of myocardial syphilis. I think a great deal can be done for these patients in spite of Dr. Conner's pessimism.

Dr. R. W. Scott, Cleveland: I do not argue that myocardial syphilis does not exist, but from a clinical standpoint, if the patient has syphilis of the aorta and the coronary arteries, if the leaflets are spared, he does not have the clinical picture of heart failure. We studied the heart tissues in hearts removed two hours after death and could not find spirochetes. The changes in the hypertrophic hearts are the same as changes in hypertrophic hearts from other causes. One cannot attribute the changes to syphilis. In regard to Dr. Kilgore's remarks as to the early roentgen-ray diagnosis of syphilis, one cannot always make such a diagnosis because the lesions may be very small in the aorta so that a roentgen-ray detection would be out of the question. By the time there is a positive finding by the roentgen ray, there is a 4 plus Wassermann reaction.

Dr. James E. Paullin, Atlanta, Ga.: In answer to Dr. Scott, as to deaths from syphilitic aortitis, the deaths were from syphilitic myocarditis. Two sudden deaths occurring with syphilitic manifestations, and infiltration, as described by Dr. Warthin a year ago, were found. In regard to the pain that these patients have in aneurysm, a negro will go for a great length of time without complaining of any pain whatever. It is difficult to get a history of pain. One man had a thoracic aneurysm with eroded vertebrae and the pain radiated into the sternum and he took it for indigestion. He did not complain of any definite pain. One day he was picked up on the street unconscious and brought to the hospital. He still did not give a history of pain. Unless one devotes time to eliciting a history of indefinite pain, one does not get it in the negro. By taking time and questioning carefully, one will find that there is substernal pain or discomfort. We have been interested in the question raised by Dr. Hamberger of prevention and treatment. Venereal disease among the negroes is considered as a minor accident in an otherwise well spent life. He does not seek relief when he can be cured but when there is marked physical disability.

Gastric and Intestinal Peristalsis

Dr. Walter C. Alvarez, Rochester, Minn.: Motion pictures show a series of rhythmic segmental movements which take place mostly in the abdomen. Sometimes there is a rush movement in the coils, the upper coils trying to hurry the food down, and the lower coils pushing it back. It surges back and forth and finally passes along. The ileocecal ring keeps the food from passing too rapidly into the lower bowel, where the movements are sluggish and much slower. The colon is apparently adapted to holding food, while the small bowel disposes of it quickly. One remarkable phenomenon is invagination of a portion of the bowel, which, in the rabbit at least, takes place frequently. A coil is sucked in; then a contraction forms below it and pushes the invaginated coil out again without any trouble.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in America for a period of three days No foreign journals are available prior to 1921, nor domestic prior to 1923 Periodicals published by the American Medical Association are not available for lending, but may be supplied on order Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

American Journal of Diseases of Children, Chicago

33: 551 704 (April) 1927

*Intracranial Tumors of Preadolescence H Cushing, Boston—p 551
Congenital Atresia of Foramen Ovale I Lehman, New York—p 585
*Neurocytoma of Suprarenal with Metastases C N Sturtevant and T C Kelly, Philadelphia—p 590
*Nontraumatic Diaphragmatic Hernia in Child J S Leopold, New York.—p 597
Chorea Use of Immune Serum J R. Gerstley and L J Wilhelmi, Chicago—p 602
*Cerebrospinal Fluid in Postdiphtheritic Paralysis J C Regan and A B Guinness, New York—p 610
*Respiratory Metabolism in Infancy and In Childhood V Effect of Moderate Exercise J R Wilson, S Z Levine, H Rivkin and I Berliner, New York—p 618
Gonorrheal Vulvovaginitis in Young S A Yesko, Washington D C.—p 630

Intracranial Tumors of Preadolescence.—Cushing analyzed 1,108 verified tumors of the brain, 154 of these having occurred in children less than 15 years of age Most of these children had cerebellar tumors, most of them had enlarged heads giving Macewen's sign on percussion, and the enlargement of the head was commonly followed by a cessation of headache, with a subjective freedom from discomforts However, in several of the cases, by the time this subjective improvement occurred, vision had begun to fail and had not infrequently been lost before the seriousness of the malady was appreciated These patients may often appear to be so well, in spite of their bouts of vomiting, that the advanced grade of choked disk may come as a total surprise, for children are not as prone as adults to complain of a slight obscuration of vision Vomiting is apt to be the dominating feature of these cases at the outset, and may be regarded as a symptom of localizing value Cushing says that a median tumor of the cerebellum is so common a lesion in preadolescence that when a child has unexplained vomiting, shows a possible enlargement of its head and gives a history of periodical unsteadiness, it is well to be on guard and to have a look at the eyegrounds every week or two

Neurocytoma of Suprarenal—Sturtevant and Kelly report a case of neurocytoma of the left suprarenal gland with metastases to the skull, dura, ribs, vertebrae, right innominata, the right femur and the liver

Nontraumatic Diaphragmatic Hernia.—Leopold's patient was 4 years of age The first symptoms were abdominal discomfort after eating, constipation and loss of weight There was no history of any injury After four weeks, symptoms and signs of an acute gastric and intestinal obstruction suddenly developed At operation all of the small intestine, most of the stomach and some of the colon were found in the thoracic cavity The hernia opening was an enlargement of the esophageal hiatus During the operation the patient stopped breathing He was revived by heart massage done through the hernial opening

Cerebrospinal Fluid in Postdiphtheritic Paralysis—The cerebrospinal fluid from fifteen cases of postdiphtheritic paralysis was studied by Regan and Guinness with regard to its macroscopic appearance, cell count, protein, sugar, chloride and acetone content, permanganate index, meningeal permeability to nitrate and colloidal benzoin reaction The colloidal benzoin reaction seems to afford a delicate test in interpreting the extent of the involvement of the nervous system in these cases

Respiratory Metabolism in Infants.—Two normal children, one subject to cyclic vomiting and one suffering from mild diabetes, have been studied by Wilson et al in the respiration chamber, during rest and exercise From the observations made, it is tentatively concluded that children with mild diabetes may be permitted restricted muscular activity without fear of increasing ketosis There is, however, some danger in permitting unlimited activity

Archives of Neurology and Psychiatry, Chicago

17. 427 570 (April) 1927

*Protein Sensitization in Epilepsy J F Ward and H A Patterson, Sonyea, N Y—p 427
*Experimental Lead Palsy P Reznikoff and J C Aub Boston—p 444
Metastatic Meningo Encephalic Carcinomatosis Without Tumefaction I H Cornwall, New York—p 466

Recent Work of Pawlow and His Pupils Conditioned Reflexes Sympathetic Nervous System (Orbeli) Epilepsy and Cerebrospinal Fluid (Speransky) W H Gantt, Leningrad, Russia—p 511

Protein Sensitization in Epilepsy—In a study made by Ward and Patterson of the occurrence of protein hypersensibility in 1,000 epileptic patients and in 100 nonepileptic controls, the incidence of protein sensitization in the Craig Colony group was found to be 37 per cent Protein sensitization was manifested in 56 8 per cent of the patients examined in the New Jersey State Village for Epileptics In the nonepileptic control group, 8 per cent showed positive reactions Raw protein extracts were employed in this study.

Experimental Lead Palsy—Experiments made by Reznikoff and Aub with isolated nerve-muscle preparations from frogs have shown that the onset of fatigue in muscles which have been exposed to lead is much more rapid and complete than normal The contractility of 'leaded" muscles is often completely lost, and recovery from fatigue is always impaired Neither lead nor fatigue alone causes palsy, both are necessary to establish the condition Experiments indicate that the physiologic lesion of lead palsy is in the muscle itself, and that the muscles which are fatigued are most susceptible to lead paralysis An attempt is made to explain susceptibility to lead palsy on the basis of the chemical and physiologic reactions between the metabolic products formed during muscular activity and lead as it occurs in the human organism

Metastatic Tumors of Brain—Twelve cases are reported by Globus and Selinsky They assert that an acute onset of cerebral symptoms, followed rapidly by the development of neurologic signs of a disseminated character and symptoms of increased intracranial tension, in the absence of changes in the disks, and positive serologic or febrile manifestations, suggests strongly a metastatic neoplastic process The probability is strengthened further by the rapid evolution of neurologic signs and the appearance of progressive wasting and of asthenia out of proportion to that usually encountered in primary tumors of the brain Under such circumstances, search should be made for the primary malignant focus

Histologic Demonstration of Phosphatides and Cerebrosides S Shapiro, New York—p 661
Dysentery G R Callender, Washington, D C—p 665

Therapeutic Action of Mercuric Chloride and Sulpharsphenamine.—It is suggested by Goldzieher and Peck that the therapeutic effects of mercuric chloride and sulpharsphenamine are based on stimulation of reticulo-endothelial function The reticulo endothelial cells of the liver and spleen respond to these drugs with marked swelling and vacuoli formation These changes subside quickly, and are followed by proliferation There is also a marked increase of phagocytic activity in the Kupfter cells, as well as in the reticulum cells of both the pulp and the follicles of the spleen

Lowering Blood Pressure Caused by Epinephrine.—Two methods, namely, blood letting combined with inhalation of amyl nitrite, and injection of sodium nitrite followed by inhalation of amyl nitrite, were used by Barksdale in an attempt to diminish the increase in blood pressure that results from the intravenous injection of epinephrine hydrochloride and of caffeine While it was not possible by either of these methods to prevent the increase in blood pressure, both greatly hastened the return of the blood pressure to normal.

Influence of Administration of Cod Liver Oil to Mother on Development of Rickets in Infant A A Weech, Baltimore—p 244.

Etiology of Puerperal Infection.—In the course of a study of the bacterial flora of the female generative tract during pregnancy, labor and the puerperium, Harris and Brown have encountered in six patients an organism which, apparently, has not heretofore been described In five instances they were able to isolate this organism in pure culture; in the sixth case, the culture was lost but the organism was identified by the organisms obtained from the other five patients. The organism closely resembled *Actinomyces necrophorus.* It differs from the latter in being nonhemolytic when grown in the blood agar plate, and in failing to ferment lactose The two organisms do not cross-agglutinate in immune serum.

Physical Relation of Cells in Tissue Cultures.—The evidence presented by Kredel for the anatomic independence of cells in the tissues of the chick may be summarized as follows. The effect of a mechanical injury at the surface of a cell is transmitted rapidly throughout the cell, but does not appear to affect adjacent cells. As it coagulates, an injured cell loses its adhesiveness for other cells. This latter fact indicates the importance of surface tension in the natural adhesiveness of cells The conclusion is drawn that, in the chick, cells of mesenchyme, amniotic ectoderm, smooth muscle, endoderm of the intestine, liver, endothelium, and epithelium of the skin are held together by simple adhesion and not by fusion or by intercellular protoplasmic bridges

Absorption of Toxic Substance of Normal Goat Serum by Guinea Pig Tissue J D Aronson, Philadelphia—p 289
Bacteriophage Antibacteriophage Reaction E Weiss, Chicago—p 301.
Bacteriophage Purified with Lipoids. E. Weiss, Chicago—p 311.

Perennial Treatment of Pollen Hay-Fever.—A modification of the specific treatment of hay-fever is presented by Brown, consisting in a distribution of the injections at three to four week intervals, throughout the year, instead of the usual preseasonal injections at from five to seven day intervals. The few constitutional reactions observed in the treatment are not sufficient to contraindicate its use.

Blood Grouping of Eskimos.—Of the polar Eskimos studied by Heinbecker and Pauli, 80 65 per cent fall into group I. Those falling into groups II, III and IV were generally shown to be half-breeds.

Skin Sensitiveness of Tuberculous Guinea-Pigs.—Freund found that young, experimentally infected, guinea-pigs show slight, if any, reaction to the injection into the dermis of a watery extract of *B. tuberculosis,* despite the presence of gross lesions of tuberculosis in the regional lymph nodes and in the spleen. The adult mother pigs, infected under the same conditions, when injected with the same extract show at the site of injection marked redness, edema and necrosis.

Michigan St. Med. Soc. Journal, Grand Rapids

26: 223 278 (April) 1927

Phases of Local Anesthesia. J. S. Lundy, Rochester, Minn—p. 223.
Tuberculosis as Systemic Disease. E. Loewenstein, Vienna.—p. 236.
Treatment of Dermatomycoses with Iodine. W. L. Chandler, East Lansing—p 244
*Subacute Bacterial Endocarditis. F. J. Smith and D. M. Brumfiel, Detroit—p 245
Vitamins and Health: Chronologic Study of Vitamins from 1915. L. J. Burch, Mt Pleasant—p. 250.

Subacute Bacterial Endocarditis.—Twenty-eight cases are analyzed by Smith and Brumfiel. There was a history of acute rheumatic fever and tonsillitis in fourteen; scarlet fever in five; chorea in two; oral sepsis in ten, and influenza in four. Asthenia was the initial symptom in ten cases; headache in four; abdominal pain in four; cough in five cases Of twenty-one cases in which a positive blood culture was obtained once or more, the organism was identified as *Streptococcus viridans* in all but two cases. Circumstantial evidence indicates, in many of the patients, that the tonsils, paranasal sinuses and abscessed teeth seem the most likely avenues to the blood stream. It is rather striking that the general experience of others in finding that a large percentage of periapical abscesses yield pure cultures of *Streptococcus viridans* was substantiated in certain of the cases by the recovery of an organism identical with that obtained from the circulating blood Certain symptoms tended to prevail; in twenty-seven cases there was asthenia; in eighteen, loss of weight, in twelve, anorexia; in eight, arthritis, and in fourteen, dyspnea Some degree of recognizable anemia appeared in eighteen, obvious malnutrition in fourteen; a demonstrable cardiac lesion in all; demonstrable clubbing of the fingers in thirteen, petechial hemorrhages in twenty-two, and the spleen was palpable in eleven of the twenty-eight. There was sufficient clinical evidence to warrant the diagnosis of aortic insufficiency in nine cases; aortic stenosis in one; mitral insufficiency in twenty-one; mitral stenosis in fifteen; and congenital defects of the heart were suspected in four. Twenty-four cases showed unmistakable evidence of embolism. Albuminuria appeared in twenty-one cases. Treatment proved unsatisfactory.

Wisconsin Medical Journal, Milwaukee

26: 187 236 (April) 1927

Cestode Families Monticellidae and Ichthyotaeniidae T J Meggitt —p 69.

Type of Tubercle Bacillus in Trinidad—Examination by Pawan of the sputum from forty different adults suffering from pulmonary tuberculosis in Trinidad revealed in every instance the human type of tubercle bacillus The cultural characteristics and the results of animal inoculation did not differ in any way from those seen in temperate climes. Bovine tuberculosis exists among bovines in Trinidad

Opisthorchis Felineus in Siam—Prommas relates the case of a boy, aged 17, who had fever, loss of appetite with abdominal pain, and passed frequent yellowish, watery stools The red blood count was 2 330 000, leukocytes, 21,600, polymorphonuclear leukocytes, 91 per cent; small lymphocytes, 8 per cent; transitionals, 1 per cent The blood was negative for malarial parasites The stool was examined once and was negative The boy died At postmortem examination the liver was greenish, and slightly enlarged The capsule was smooth On incision more than a thousand flat thin worms were found in practically every bile duct, even in the common duct, and in the gallbladder. These worms proved to be *Opisthorchis felineus*

Infection with Lagocheilascaris Minor.—Pawan's patient, a native of Trinidad, had a discharging mass on the side of the neck of eight years' duration From it escaped continuously large numbers of *Lagocheilascaris minor*, which is found in subcutaneous abscesses in Trinidad, in Dutch Guiana and in the intestine of the cloudy leopard (*Felis nebulosa*) of South America

Brain, London

50:1 112 (March) 1927

*Endocrines in Epilepsy H I Schou and W Susman —p 53
Cerebellar Terminations of Spinocerebellar Fibers of Lower Lumbar and Sacral Segments of Cat G M Beck —p 60

Diffuse Periaxial Encephalitis — Three new cases of Schilder's form of encephalitis are described by Stewart et al The patients were aged 8, 3 and 43 years, and the length of disease was eighteen months, three months and nine days, respectively In one case the first symptom was deafness in another, the initial blindness was associated with papillitis and was due to demyelination of the optic nerves

Manganese Toxemia.—Seven cases of manganese poisoning are described by Charles The suggestion is made that the nervous phenomena are due to deficiency of a hepatic hormone Some benefit was obtained in a few cases from treatment with liver.

Endocrines in Epilepsy.—Various endocrines, the genital glands from six cases, and the liver from one case of epilepsy were examined by Shou and Susman Deviations from the normal were present All organs examined in the first five cases gave ample evidence of perivascular necrosis The sixth, a mild case, did not show such lesions That there are significant lesions in these cases is obvious Hypertrophy was a feature of the parathyroids, the pituitaries and the islets of Langerhans The liver, the islets of Langerhans, the pituitary and the suprarenal all showed lesions This was also true of the acinar tissue of the pancreas The pathologic agent has a selective action on chromophil cells, as seen in the suprarenals and pituitaries A toxic necrosis is present in the perivascular channels of all the organs examined, if the case has been a severe one

Journal of State Medicine, London

Securing Cooperation of Fathers in Child Welfare D H Geffen —p 224
Aspects of Industrial Welfare Work G Smith —p 228

Defects of Reading and Writing—According to Critchley many cases of gross reading defect in children who are otherwise of normal intelligence are, in reality, instances of congenital word blindness This anomaly comprises an inability to grasp the significance which is conventionally attached to graphic symbols, it is possible that a maldevelopment of the angular gyri constitutes the anatomic basis for this defect Many of these children are ambidextrous, and their left handed efforts at writing tend to conform to the mirror writing type This is due to the uncontrolled activity of the kinesthetic or corrective supervision of the visual imagery.

Rupture of Umbilical Cord Before Birth F M Morris —p 119

Etiology of Pulmonary Thrombosis—Cohen is convinced that micro-organisms play a great if not the leading part in thrombosis Eleven cases out of eighteen in which a bacteriologic investigation was made showed streptococci to predominate

Tooth Extraction; Cerebral Abscess.—Robson relates the case of a man who had had typical attacks of migraine for four years, the seat of maximum intensity of the headache being in the left temporal region Dental roentgenograms showed many areas of periapical necrosis, and extensive absorption of perialveolar bone Four teeth were extracted under local anesthesia On the third day, four more teeth were extracted On the fourth day, after a violent sneeze, the patient discovered that the vision on the right side had gone By the sixth day, the headache had become constant and of a boring character and nothing short of morphine afforded relief He had a rigor in the morning The loss of vision was discovered to be a bilateral homonymous hemianopia On the tenth day, lumbar puncture was performed, and the fluid, quite clear, came off under considerable pressure A provisional diagnosis of cerebral abscess was made Finally, coma supervened and death ensued on the eleventh day At the necropsy an acute abscess about the size of a hen's egg was found in the occipital lobe

Pharmacodynamic Researches on the Oculocardiac Reflex. J. Kreis.—p. 50.
*Cyclic Vomiting with Acetonemia. M. Labbé.—p. 82.

Pathogenesis of Cyclic Vomiting with Acetonemia.—In Labbé's case a young girl developed considerable acidosis and uncontrollable vomiting on the occasion of a mild attack of appendicitis. Large amounts of ammonia, amino-acids, acetone bodies and organic acids were found in the urine. There were also urobilin and bile. Investigation revealed attacks of cyclic vomiting in childhood. On each occurrence of vomiting, acidosis was the prevailing symptom. Acidosis results from disturbances in fat metabolism, due to lesions of the liver. In a fatal case, death occurs not from acidosis but from degeneration and consequent insufficiency of the liver. The disease should be differentiated from appendicitis and from meningitis. The latter may be accompanied by acidosis; on the other hand, attacks of cyclic vomiting may be complicated by meningeal reactions. Treatment with alkalis does not cure, but brings about improvement. The action of insulin is unappreciable.

*Emotivity and Anguish in Colitis with Acid Fermentation. R. Savignac and R. Sarles.—p. 44.

Emotivity and Anguish in Colitis with Acid Fermentation.—Savignac and Sarles have frequently observed emotivity and mental anguish in cases of colitis with fermentation and formation of large amounts of organic acids in the intestinal contents. Phenomena of irritation of the vegetative system were present. Of 172 patients with this kind of colitis, the mental condition mentioned was observed in 71 per cent. In 8 per cent, the syndrome of depression prevailed. Increase in intestinal acids modifies the acid-base balance of the blood, favoring the appearance of mental and nervous phenomena in patients with a corresponding nervous constitution. Subsidence of the colitis is followed by disappearance of the emotivity and anguish.

Rôle of Placental Epithelium. G. Chappaz.—p. 39.

Pathogenesis and Treatment of Pains in the Bones in the Menopause.—Dalsace and Guillaumin point out that the natural or induced menopause is sometimes the origin of pains simulating chronic arthritis. These pains become exacerbated during the night; especially on voluntary movements. They are located in the bones rather than in the joints, and are frequently associated with muscular weakness. Joint deformities are not observed. Examination of the blood reveals a decrease in calcium and phosphorus. The pains tend to disappear spontaneously in from eight to sixteen months. Nevertheless, active treatment is required, since they may represent the first stage of arthritis deformans. Logically the treatment consists in restoration of salts to the body tissues. The authors use phosphorus by preference. Two teaspoonfuls of a solution containing 10 Gm. of phosphoric acid in 100 Gm. of water are given daily. Cod liver oil mixed with phosphorus and epinephrine may also be of use in combating the mineral deficiency. The effect of this treatment is greatly enhanced by ultraviolet rays. Ovarian extract alone proved to be without influence.

Journal de Physiol. et de Pathol. Générale, Paris

24: 701-1048 (Dec.) 1926. Partial Index

*Changes in White Blood Corpuscles During Work. A. F. Goldberg and M. V. Lepskaia.—p. 715.
*Effect of Anticoagulants on the T-Ventricular Complex. J. Freud.—p. 725.
By-Effects of Heterogenic Transfusions and Shock. R. Cruchet and J. Caussimon.—p. 762.
*Natural Lysis of Tubercle Bacilli in Sputum. C. Richet, Jr., et al.—p. 788.

Changes in White Blood Corpuscles During Physical and Mental Work.—Goldberg and Lepskaia examined the blood of 300 healthy persons during physical and mental work. In both the number of leukocytes increased, especially that of the neutrophils, which reached 82 per cent. The lymphocytes and eosinophils were reduced; the eosinophils disappeared entirely when the work was prolonged. The number of basophils and of monocytes increased; neutrophil myelocytes, plasmocytes and Türck's cells appeared. The changes in the leukocyte picture are ascribed to irritation of the hematopoietic organs by products of an accelerated nitrogen metabolism in muscular exercise, and by products of an accelerated phosphorus metabolism in mental exercise. The phenomena were more pronounced in intellectual work than in physical work. There was return to normal in about two hours.

Effect of Anticoagulating Substances on the Aspect of Electrocardiograms.—Freud's experiments tended to demonstrate a correlation between the T-ventricular complex and the capillary circulation. For this purpose dogs were injected intravenously with various anticoagulants. The electrocardiograms showed a longer duration and a larger amplitude of the T wave. Owing to reduced coagulability of the blood plasma, the quantity of liquid blood increases. A greater effort is then required on the part of the circulatory motor apparatus. The theory is that the increase in the motor functioning is limited to the aortic bulb and to the supravalvular portion of the aorta during the T-wave phase.

Natural Bacteriolysis in Tuberculous Sputums.—Researches were made by Richet, Hauduroy and Delbreil on sputums of twenty-nine tuberculous patients. In 28 per cent of the sputums, treated with heat, the bacilli disappeared, as far as their visible forms were concerned. The bacteriolysis started after two or three days; it was accomplished in from ten to fifteen days. Guinea-pigs inoculated with these sputums did not develop tuberculosis. A series of the sputums were diluted with sodium chloride solution or peptonized water previous to the exposure to heat. The lysis of the tubercle bacilli was enhanced by this treatment; it was also enhanced by previous sterilization. The bacteriolysis was most frequent in sputums of patients who were improving; it was sometimes observed in sputums of patients in the preagonal stage. The authors think that the lysis is due to a thermostable, nonfiltrable principle, and not to a thermolabile ferment or to a bacteriophage. This principle may take part in the defense of the lungs against tubercle bacilli.

Journal de Radiologie et d'Électrologie, Paris

11: 1-80 (Jan.) 1927

*Roentgen-Ray Diagnosis in Gynecology. R. Grégoire et al.—p. 1.
Roentgen-Ray Examination of Uterus and Tubes Following Lipiodol Injection. G. Cotte and P. Bertrand.—p. 24.
Ossification Points in the Knee of the New-Born. R. Jardin.—p. 30.

Roentgen-Ray Diagnosis in Gynecology.—Grégoire, Béclère and Darbois emphasize the fact that intra-uterine injection of lipiodol is harmless under a pressure of 30 cm. of mercury. With this injection roentgen-ray pictures valuable in diagnosis of pelvic tumors, metrorrhagias and tubal permeability can be obtained. In case of fibroma the uterine cavity appears enlarged and deformed. In case of cyst, the uterine image is normal, the tubes are permeable, the seat of the lesion being on one side. Considerable deviation of the uterus or fallopian tubes suggests intraligamentous tumor. In case of tubal tumors, a distended and obliterated oviduct is visible in the roentgenograms. In metrorrhagias, changes may appear in the uterine cavity or in the uterine contour. The seat of the lesion can thus be established exactly. Roentgen rays are most valuable in examination of tubal permeability. The paper contains a detailed description of the technic used; the indications are discussed and results recorded.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE, 1927

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in the United States and to Fellows of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No foreign journals are available prior to 1922, nor domestic journals prior to 1923. Requests for periodicals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in The Journal. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "Ml," Medicolegal; "P," Propaganda for Reform; "ME," Medical Economics; "ab," abstract; the star (*) indicates an original article in The Journal.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Society Proceedings" are indexed under these titles at the end of the letters "B," "D," "M" and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2254.
